Citrix ADC 13.1 Advanced Policy Expression Reference

To construct an expression by using this document, start by clicking one of the prefixes listed below.Then, select an expression from the list of available expressions and click the "Returns" link to view the expressions that you can further apply on the data.

AAA	Denotes the AAA context of the current transaction.
ANALYTICS	Provides access to analytics information and operations.
CLIENT	Designates an expression that refers to the client. This is the starting point for access into parameters such as Ether and SSL.
CONNECTION	Designates an expression that refers to network packet irrespective of flow
DIAMETER	Models the DIAMETER message.
DNS	Models the DNS message.
EXTEND	Extends the target area around the matched pattern.
HTTP	Models the HTTP message.
ICA	Models the ICA protocol.
ICAP	Models the ICAP message.
MQTT	Models the MQTT message.
MSSQL	Models the MSSQL protocol.
MYSQL	Models the MYSQL protocol.

ORACLE	Models the ORACLE protocol.
QUIC	Models the QUIC message.
RADIUS	Models the RADIUS message.
SERVER	Designates an expression that refers to the server. This is the starting point for access into parameters such as Ether and SSL.
SIP	Models the SIP protocol.
SMPP	Models the SMPP protocol.
SUBSCRIBER	Models the Subscriber database attributes.
SYS	Designates an expression that refers to the NetScaler, rather than the client or server.
TARGET	Refers to the matched pattern.
TEXT	Operates on selected text.
URL	URL provides operations for parsing and operating on the URL. The supported format is [<protocol>://<hostname>]<path>[?<query>]. The Text object backing a HTTP URL object has the Text Mode set to URLENCODED by default.</query></path></hostname></protocol>

AAA_AUTHENTICATION_T

Operates on AAA authentication information.

This topic lists the expressions that are provided by this class.

- `ERROR`

  Returns error encountered in current authentication factor.

`Returns:` authentication_error_e

- `NONCE`

  Returns nonce for current authentication factor.

`Returns:` text_t

AAA_LOGIN_T

Operates on AAA login request information

This topic lists the expressions that are provided by this class.

- `CLIENT_MAC_ADDR`

  Returns one MAC address at a time (sequentially) from the list of MAC addresses returned by a client as part of the MAC-ADDR header.

`Returns:` text_t

- `DOMAIN`

  Returns the domain of the user. This is the domain used at the time of login

`Returns:` text_t

- `PASSWORD`

  Returns the password of the user. This is the password used at the time of login

`Returns:` text_t

- `PASSWORD2`

  Returns the password2 of the user. This is the password2 used at the time of login

`Returns:` text_t

- `RELAYSTATE`

  Returns the relaystate value, which is fetched from the SAML Response. It may return NULL if relaystate in the response is empty

`Returns:` text_t

- `SAML_REQ_ACS_URL`

Returns the ACS URL received in the SAML Request associated with the current login request. The value is extracted at the time of processing the SAML Request. Returns NULL if the SAML Request or the ACS URL is not found.

`Returns:` text_t

- `USERNAME`

  Returns the name of the user. This is the name used at the time of login

`Returns:` text_t

`VALUE` (text_t name)

Returns the value associated with the parameter name. The value is extracted at the time of login from the name-value pair within the POST body

`Parameters` (expressions not allowed)`:`

name- the name of the name-value pair whose value is to be extracted

`Returns:` text_t

AAA_T

Operates on AAA information.

This topic lists the expressions that are provided by this class.

- `AUTHENTICATION`

  Returns AAA authentication information.

`Returns:` aaa_authentication_t

- `LOGIN`

  Returns the AAA login request information.

`Returns:` aaa_login_t

- `USER`

  Returns the AAA User associated with the current transaction.

`Returns:` aaa_user_t

AAA_USER_T

Represents the AAA User Information.

This topic lists the expressions that are provided by this class.

`ATTRIBUTE` (`uint` index)

Returns USER's attribute stored at a given index. For example: HTTP.REQ.USER.ATTRIBUTE(1) gives the value of a previously extracted attribute that is stored as 'attribute1'. Index range is between 1 and 16, both included.

`Parameters``:`

index- offset

`Returns:` text_t

`ATTRIBUTE` (text_t name)

Returns USER's attribute stored with a given name. For example: HTTP.REQ.USER.ATTRIBUTE("name") gives the value of a previously extracted attribute that is stored as 'attribute\["name"\]'.

`Parameters``:`

name- name used for extracting corresponding attribute value

`Returns:` text_t

- `AUTH_STRENGTH`

  Returns an integer that represents the strength of authentication of the current user session.

`Returns:` num_at

- `DOMAIN`

  Returns the Domain of the user.

`Returns:` text_t

- `EXTERNAL_GROUPS`

  Operate as a List on the External Groups which is seperated by ','. For example: HTTP.REQ.USER.EXTERNAL_GROUPS gives list of all groups which are ',' seperated.

`Returns:` list_t

`EXTERNAL_GROUPS` (`char` sep)

Operate as a List on the Group which is seperated by given delimiter. For example: HTTP.REQ.USER.EXTERNAL_GROUPS(':') gives list of all external groups which are ':' seperated.

`Parameters` (expressions not allowed) `:`

sep- delimiter

`Returns:` list_t

- `GROUPS`

  Operate as a List on the Group which is seperated by ','. For example: HTTP.REQ.USER.GROUPS gives list of all groups which are ',' seperated. In this list first internal groups are listed which are followed by external groups.

`Returns:` list_t

`GROUPS_AS_XML` (text_t tag)

Gives the list of groups in a SAML assertion multi-attribute format, each enclosed by an element that has the specified tagname. For example: HTTP.REQ.USER.GROUPS_AS_XML("mytagname"): the expression will return a list of groups in the following format - financeengg In this example, finance, engg are the group names.

`Parameters``:`

tag- tagname

`Returns:` text_t

`GROUPS` (`char` sep)

Operate as a List on the Group which is seperated by given delimiter. For example: HTTP.REQ.USER.GROUPS(':') gives list of all groups which are ':' seperated. In this list first internal groups are listed which are followed by external groups.

`Parameters` (expressions not allowed) `:`

sep- delimiter

`Returns:` list_t

- `INTERNAL_GROUPS`

  Operate as a List on the Group which is seperated by ','. For example: HTTP.REQ.USER.INTERNAL_GROUPS gives list of all groups which are ',' seperated.

`Returns:` list_t

`INTERNAL_GROUPS` (`char` sep)

Operate as a List on the Group which is seperated by given delimiter. For example: HTTP.REQ.USER.INTERNAL_GROUPS(':') gives list of all internal groups which are ':' seperated.

`Parameters` (expressions not allowed) `:`

sep- delimiter

`Returns:` list_t

`IS_MEMBER_OF_ALL` (text_t patset_name)

Returns TRUE if all patterns(group string) of the patset matches user's groups in session

`Parameters` (expressions not allowed) `:`

patset_name- patset Name

`Returns:` bool_at

`IS_MEMBER_OF_ANY` (text_t patset_name)

Returns TRUE if there is at least one pattern(group string) of the patset matches user's groups in session

`Parameters` (expressions not allowed) `:`

patset_name- patset Name

`Returns:` bool_at

`IS_MEMBER_OF` (text_t group_name)

Returns TRUE if the user is a member of the group group_name

`Parameters` (expressions not allowed) `:`

group_name- Group Name

`Returns:` bool_at

- `LOGIN_ATTEMPTS`

  Return the number of failed login attempts for the current user. User name is extracted from current authentication process.

`Returns:` num_at

`LOGIN_ATTEMPTS` (text_t username)

Return the number of failed login attempts for the given user.

`Parameters` (expressions not allowed) `:`

username- the name of the user to get the information for.

`Returns:` num_at

- `LOGIN_NAME`

  Returns the NAME that is provided by user at the time of login.

`Returns:` text_t

- `NAME`

  Returns the NAME of the user. This is the name used by user for login unless it is overriden by name from external authentication server.

`Returns:` text_t

- `OAUTHIDP_CC_FLOW`

  Returns true if the AAA session is in the OAuth IDP CC Flow. This is used during authentication of the user when the AAA server acts as an IDP and the Relaying Party is Citrix Cloud. Note

that this expression works only if the corresponding OAuth IDP profile is configured with a default group.

`Returns:` bool_at

- `OAUTHIDP_FLOW`

  Returns true if the AAA session is in the OAuth IDP Flow. This is used during authentication of the user when the AAA server acts as an IDP. Note that this expression works only if the corresponding OAuth IDP profile is configured with a default group.

`Returns:` bool_at

- `PASSWD`

  Returns the PASSWORD of the user.

`Returns:` text_t

- `SAMLIDP_FLOW`

  Returns true if the AAA session is in the SAML IDP Flow. This is used during authentication of the user when the AAA server acts as an IDP. Note that this expression works only if the corresponding SAML IDP profile is configured with a default group.

`Returns:` bool_at

- `SESSIONID`

  Returns the Session ID of the user.

`Returns:` text_t

ALPN_T

ALPN extension in client hello message of SSL handshake.

This topic lists the expressions that are provided by this class.

`HAS_NEXTPROTOCOL` (text_t nextproto)

Returns true if ALPN extension in the client hello message has given next protocol.

`Parameters` (expressions not allowed) `:`

nextproto- ALPN protocol

`Returns:` bool_at

ANALYTICS_T

Designates an expression that refers to the analytics. This is the starting point for access into parameters such as stream.

This topic lists the expressions that are provided by this class.

- `CONNECTION_QUALITY`

  Accesses Connection Quality Analytics metrics evaluated for client.

`Returns:` cqa_t

`STREAM` (text_t identifier_name)

Operates on a stream identifier specified in the stream method.

`Parameters` (expressions not allowed) `:`

identifier_name- Name of the stream identifier added using add stream identifier.

`Returns:` stream_t

AUTH_KEYID_T

Represents the Authority Key Identifier Extension of the X509V3 certificate.

This topic lists the expressions that are provided by this class.

- `CERT_SERIALNUMBER`

  Returns the SerialNumber field of the Authority Key Identifier as a blob.

`Returns:` text_t

- `EXISTS`

  Returns boolean TRUE if the Authority Key Identifier extension exists in the certificate, otherwise returns boolean FALSE.

`Returns:` bool_at

- `ISSUER_NAME`

  Returns the Issuer Distinguished Name as a '/' seperated Name-Value pair list, where '=' seperates the Name and the Value. Example: /C=IN/ST=KA/L=BLR/O=Netscaler Pvt Ltd/OU=www.netscaler.com/CN=www.netscaler.com/emailAddress=ns@ns.com

`Returns:` nvlist_t

- `KEYID`

  Returns the keyIdentifier field of the Authority Key Identifier as a blob.

`Returns:` text_t

AUTHENTICATION_ERROR_E

This object represents one of the error codes that is encountered during authentication.

Enumerations

INVALID_CREDS

This error represents invalid credentials presented for authentication.

NOT_PERMITTED

This error represents user is not permitted to login.

SYS_TIMEOUT

This error represents timeout during authentication process at external authentication server.

SYS_ERROR

This error represents processing error at external authentication server.

SOCKET_ERROR

This error represents connection error at external authentication server.

BAD_USER

This error represents login attempt for invalid username.

BAD_PASSWORD

This error represents login attempt for invalid password.

MISMATCH_PASSWORD

This error represents password mismatch for current login attempt.

INVALID_USER

This error represents username used for login does not exist or incorrect.

RESTRICTED_HOURS

This error represents login attempt in restricted time.

ACCOUNT_DISABLED

This error represents account is disabled for current user.

PASSWORD_EXPIRED

This error represents password is expired for the current user.

NO_DIALIN_PERM

This error represents user does not have dial-in permissions.

CHANGE_PASSWORD

This error represents error while trying to change password.

ACCOUNT_LOCKED

This error represents user's account is locked out.

This topic lists the expressions that are provided by this class.

`EQ` (authentication_error_e e)

The result is Boolean TRUE if the input argument is equal to the error presented by this object.

`Parameters` (expressions not allowed) `:`

e- Authentication Error enumeration

`Returns:` bool_at

`NE` (authentication_error_e e)

The result is Boolean TRUE if the input argument is not equal to the error presented by this object.

`Parameters` (expressions not allowed) `:`

e- Authentication Error enumeration

`Returns:` bool_at

AVP_T

Operations that can be performed on the returned AVPs.

`Note:` An AVP can have multiple instances in a Diameter message. However, the system can access only the first 16 instances.

`Example:`

- To get the first value of AVP code 266 from a request, use: DIAMETER.REQ.AVP(266).VALUE(0).
- To get the fourth value of AVP code 266 from a request, use: DIAMETER.REQ.AVP(266).VALUE(3).
- To check if AVP code 1000 in the response has the vendor-specific bit set, use: DIAMETER.RES.AVP(1000).IS_VENDOR_SPECIFIC.

This topic lists the expressions that are provided by this class.

`*Note` *: Expressions with the * symbol are inherited / promoted from text_t

- `AVPLIST_AFTER`

  Returns the region after this AVP in diameter message (or in other words returns location at end of this AVP and length covering end of this AVP to end of diameter message. If this AVP is inside a Grouped AVP, this method returns region after this AVP in parent Grouped AVP.

`Returns:` text_t

`*AVPLIST_BEFORE`

Returns the region till this AVP in diameter message (or in other words returns location at start of AVPs and length equal to offset of this AVP). If this AVP is inside a Grouped AVP, this method returns region till this AVP in parent AVP.

`Returns:` text_t

`*AVP` (`uint` avpcode)

Returns the AVP nested inside the GROUPED AVP (the Data field is a sequence of AVPs).

For example, to retrieve AVP(263) that is nested in AVP(99999) in a request, the expression is: DIAMETER.REQ.AVP(999999).AVP(263).

`Parameters` (expressions not allowed) `:`

avpcode- AVP code

`Returns:` avp_t

`*AVP` (`uint` avpcode, `uint` vendorid)

Returns the specified AVP in given vendor-id namespace and that is nested inside a GROUPED AVP in the message.

For example, to get the AVP with code 1005 and VendorId 10415 from a Request, that is nested inside 1001 (vendor-id 10415). Use this expression: DIAMETER.REQ.AVP(1001, 10415).AVP(1004, 10415).

`Note:` To get AVP that is nested inside a grouped AVP, use the AVP method from the avp_t class.

`Parameters` (expressions not allowed) `:`

avpcode- AVP code

vendorid- Vendor Id

`Returns:` avp_t

`*COUNT`

Returns the number of occurences of an AVP in diameter message. The system does not keep track of more than 16 AVP occurences of an AVP. The result will be undefined if there are more than 16 instances of that AVP.

`Returns:` num_at

`*EXISTS`

Returns true if the AVP exists in the message.

`Returns:` bool_at

`*INSTANCE` (`uint` instanceno)

Returns instances of the AVP.

The first instance of the AVP can be retrieved by simply using the expression: DIAMETER.REQ.AVP(266). However, subsequent instances must be retrieved using this method.

INSTANCE(0) retrieves the first instance, INSTANCE(1) retrieves the second instance, and so on.

For example, lets assume the Route-Record AVP (code 282) has three instances in a request.

- Route-Record: abcd1.netscaler.com
- Route-Record: abcd2.netscaler.com
- Route-Record: abcd3.netscaler.com

To get the second instance, the expression would be: DIAMETER.REQ.AVP(282).INSTANCE(1).

`Parameters` (expressions not allowed) `:`

instanceno- AVP instance number. Maximum value: 15.

`Returns:` avp_t

`*IS_MANDATORY`

Returns true if the AVP has the Mandatory bit set.

`Returns:` bool_at

`*IS_VENDOR_SPECIFIC`

Returns true if the AVP has Vendor-Specific bit (V) set.

`Returns:` bool_at

`*LENGTH`

Returns the AVP length including AVP header.

If the AVP is not present, it returns length 0. If multiple occurences of the AVP exist, it returns the length of first occurence.

`Returns:` num_at

`*TYPECAST_TEXT_T`

Convert avp_t to text_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (text_t : Designates any piece of text.)

`Returns:` text_t

`*VALUE`

Returns the value of first instance of the AVP as OctetString..

For example, lets assume the Route-Record AVP (code 282) has three instances in a request.

- Route-Record: abcd1.netscaler.com
- Route-Record: abcd2.netscaler.com
- Route-Record: abcd3.netscaler.com

To get the first instance, the expression would be: DIAMETER.REQ.AVP(282).VALUE.

Alternatively, you can use the expression: DIAMETER.REQ.AVP(282).

`Returns:` text_t

`*VALUE` (`uint` instanceno)

Returns value of an instance of the AVP.

The first instance of the AVP can be retrieved by simply using the expression: DIAMETER.REQ.AVP(266). However, subsequent instances must be retrieved using this method.

VALUE(0) retrieves the first instance, VALUE(1) retrieves the second instance, and so on.

For example, lets assume the Route-Record AVP (code 282) has three instances in a request.

- Route-Record: abcd1.netscaler.com
- Route-Record: abcd2.netscaler.com
- Route-Record: abcd3.netscaler.com

To get the second instance, the expression would be: DIAMETER.REQ.AVP(282).VALUE(1).

`Parameters` (expressions not allowed) `:`

instanceno- AVP instance number. Maximum value: 15.

`Returns:` text_t

`*VENDOR_ID`

Returns the Vendor ID if the AVP has the Vendor-Specific bit set.

`Returns:` unsigned_long_at

`*AFTER_REGEX` (`re` regex)

Selects the text after the portion that matches the given regular expression argument. The first match is returned when multiple matches occur in the text. The match may occur anywhere within the text - if you wish to "anchor" this, use "\^" at the start of the regex and/or "$" at the end of the regex. When the regular expression does not match the given string, a Text object of length of 0 is returned.

Example: HTTP.REQ.HEADER("etag").AFTER_REGEX(re/KX/) will select "DAPPER" from "KXDAPPER". This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

regex- Regular Expression

`Returns:` text_t

`*AFTER_STR_ANY` (text_t patset_name)

Selects the Text that is present after the first occurrence of any of the strings that are bound to the patset named by the string argument. If there is no match to any of the strings bound to the patset in the current Text object then the result Text object has 0 length. The patset cannot have strings longer than 255 characters. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` text_t

`*AFTER_STR` (text_t s)

Selects the Text that is present after the first occurrence of the string argument. If there is no match for the argument in the current Text then the result Text object has 0 length. The input string cannot be bigger than 255 characters. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*APPEND` (bool_at b)

Appends the given boolean's string representation to the current string.

`Parameters``:`

b- the boolean value to append.

`Returns:` text_t

`*APPEND` (double_at i)

Appends the given double's string representation to the current string.

`Parameters``:`

i- the double value to append.

`Returns:` text_t

`*APPEND` (ip_address_at addr)

Appends the given IPv4's string representation to the current string.

`Parameters``:`

addr- the IPv4 address to append.

`Returns:` text_t

`*APPEND` (num_at i)

Appends the given number's string representation to the current string.

`Parameters``:`

i- the number value to append.

`Returns:` text_t

`*APPEND` (time_local_at t)

Appends the given time's string representation to the current string.

`Parameters``:`

t- the time value to append.

`Returns:` text_t

`*APPEND` (time_at t)

Appends the given time's string representation to the current string.

`Parameters``:`

t- the time value to append.

`Returns:` text_t

`*APPEND` (unsigned_long_at i)

Appends the given unsigned long's string representation to the current string.

`Parameters``:`

i- the unsigned long value to append.

`Returns:` text_t

`*APPEND` (ipv6_address_at addr)

Appends the given IPv6's string representation to the current string.

`Parameters``:`

addr- the IPv6 address to append.

`Returns:` text_t

`*APPEND` (ipv6_subnet_at addr)

Appends the given IPv6 subnet's string representation to the current string.

`Parameters``:`

addr- the IPv6 subnet to append.

`Returns:` text_t

`*APPEND` (mac_address_at addr)

Appends the given MAC's string representation to the current string.

`Parameters``:`

addr- the MAC address to append.

`Returns:` text_t

`*APPEND` (text_t str)

Appends the given string to the current string.

`Parameters``:`

str- the string to append.

`Returns:` text_t

`*APPEND` (time_at t)

Appends the given time's string representation to the current string.

`Parameters``:`

t- the time value to append.

`Returns:` text_t

`*B64DECODE`

Decodes the selected text using base64 decoding.

For example, the string "TWFu" is converted to "Man"

`Returns:` text_t

`*B64ENCODE`

Encodes the selected text using base64 encoding.

For example, the string "Man" is converted to "TWFu"

`Returns:` text_t

`*BEFORE_REGEX` (`re` regex)

Selects the text before the portion that matches the given regular expression argument. The first match is returned when multiple matches occur in the text. The match may occur anywhere within

the text - if you wish to "anchor" this, use "\^" at the start of the regex and/or "$" at the end of the regex. When the regular expression does not match the given string, a Text object of length of 0 is returned.

For example: HTTP.RES.HEADER("content-type").BEFORE_REGEX(re#/#) will select "text" from "text/plain". This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

regex- Regular Expression

`Returns:` text_t

`*BEFORE_STR_ANY` (text_t patset_name)

Selects the Text that is present before the first occurrence of any of the strings that are bound to the patset or datasetnamed by the string argument. If there is no match to any of the strings bound to the patset in the current Text object then the result Text object has 0 length. The patset cannot have strings longer than 255 characters. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` text_t

`*BEFORE_STR` (text_t s)

Selects the Text that is present before the first occurrence of the string argument. If there is no match for the argument in the current Text object then the result Text object has 0 length. The input string cannot be bigger than 255 characters. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*BETWEEN` (text_t start, text_t end)

Results in Boolean TRUE value if length of the Text object is greater than or equal to the sum of the Start and End argument lengths and if the prefix of the Text object matches the Start string argument and if the Suffix of the Text object matches the End string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

start- Start

end- End

`Returns:` bool_at

`*BIN_DECODE` (binary_encoding_e encoding)

Decode the encoded input into its original byte sequence. An incorrectly enooded input will result in an Undef error.

`Parameters` (expressions not allowed) `:`

encoding- specifies how the bytes are encoded.

`Returns:` text_t

`*BIN_ENCODE` (binary_encoding_e encoding)

Encode the input byte sequence. Note that BIN_ENCODE(hex_colons) is equivalent to BLOB_TO_HEX().

`Parameters` (expressions not allowed) `:`

encoding- specifies how the bytes are to be encoded.

`Returns:` text_t

`*BLOB_TO_HEX`

Convert to hexadecimal representation and select text.

For example, the byte string abc is converted to 61:62:63.

`Returns:` text_t

`*COMPARE` (text_t s)

Results in a Number Value which is the result of comparison of the input argument with the Text object. The result is greater than 0 if the Text object is lexicographically greater than the argument. The result is 0 if the Text object and the argument match. The result is less than 0 if the Text object is lexicographically lesser than the argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` num_at

`*CONTAINS_ANY` (text_t patset_name)

Results in Boolean TRUE value if the Text contains any of the strings that are bound to the patset or dataset named by the string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` bool_at

`*CONTAINS_INDEX` (text_t patset_name)

Returns the numerical index of the matching string, if the Text contains any of the strings that are bound to the patset or dataset named by the string argument. Returns 0 if there is no match. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` num_at

`*CONTAINS` (text_t s)

Results in Boolean TRUE value if the Text contains the string given in the argument. The input string cannot be bigger than 255 characters. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*CRC32`

Returns a 32-bit integer computed by applying a CRC (cyclic redundancy check) function to the selected text. This is the CRC function used by Ethernet, MPEG-2, PKZIP, GZIP, PNG, and many other applications. For example, the expression to compute the CRC value of the (first 1000 bytes of the) body of an HTTP request is: HTTP.REQ.BODY(1000).CRC32

`Returns:` num_at

`*DECODE_USING_TEXT_MODE`

Decodes the selected text using the currently configured text encoding methods like URLENCODED, BACKSLASH_ENCODED, PLUS_AS_SPACE, NOURLENCODED, NO_BACKSLASH_ENCODED and NO_PLUS_AS_SPACE. Text encoding methods are set using SET_TEXT_MODE method.

`Returns:` text_t

`*DECRYPT`

Decrypt the selected base64-encoded ciphertext using the configured encryptionParams.

`Returns:` text_t

`*DECRYPT` (binary_encoding_e in_encoding)

Decrypt the selected ciphertext using the configured encryptionParams.

`Parameters` (expressions not allowed) `:`

in_encoding- specifies how the input ciphertext is encoded. If the ciphertext is not encoded as specified, causes an Undef error.

`Returns:` text_t

`*DECRYPT` (text_t encryptionKey)

Decrypt the selected base64-encoded encrypted bytes using the configured encryption key.

`Parameters` (expressions not allowed) `:`

encryptionKey- identifies the encryptionKey object to provide the cipher method, mode, padding, key, encrypted format and optional initialization vector (IV).

`Returns:` text_t

`*DECRYPT` (text_t encryptionKey, binary_encoding_e in_encoding)

Decrypt the selected base64-encoded encrypted bytes using the configured encryption key.

`Parameters` (expressions not allowed) `:`

encryptionKey- identifies the encryptionKey object to provide the cipher method, mode, padding, key, encrypted format, and optional initialization vector (IV).

in_encoding- specifies how the input ciphertext is encoded. If the ciphertext is not encoded as specified, causes an Undef error.

`Returns:` text_t

`*DIGEST` (digest_method_e method)

Returns a byte sequence computed by applying the the specified message digest method to the selected text.

`Parameters` (expressions not allowed) `:`

method- digest method to apply to the input text

`Returns:` text_t

`*ENCRYPT`

Encrypt the selected plaintext bytes using the configured encryptionParams. The resulting ciphertext is base64-encoded.

`Returns:` text_t

`*ENCRYPT` (binary_encoding_e out_encoding)

Encrypt the selected plaintext bytes using the configured encryptionParams.

`Parameters` (expressions not allowed) `:`

out_encoding- specifies how the resulting ciphertext is encoded.

`Returns:` text_t

`*ENCRYPT` (text_t encryptionKey)

Encrypt the selected cleartext bytes using the configured encryption key.

`Parameters` (expressions not allowed) `:`

encryptionKey- identifies the encryptionKey object to provide the cipher method, mode, padding, key, encrypted format and optional initialization vector (IV).

`Returns:` text_t

`*ENCRYPT` (text_t encryptionKey, binary_encoding_e out_encoding)

Encrypt the selected cleartext bytes using the configured encryption key.

`Parameters` (expressions not allowed) `:`

encryptionKey- identifies the encryptionKey object to provide the cipher method, mode, padding, key, encrypted format and optional initialization vector (IV).

out_encoding- specifies how the resulting ciphertext is encoded.

`Returns:` text_t

`*ENDSWITH_ANY` (text_t patset_name)

Results in Boolean TRUE value if the Text ends with any of the strings that are bound to the patset or dataset named by the string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` bool_at

`*ENDSWITH_INDEX` (text_t patset_name)

Returns the numerical index of the matching string, if the Text ends with any of the strings that are bound to the patset or dataset named by the string argument. Returns 0 if there is no match. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` num_at

`*ENDSWITH` (text_t end)

Results in Boolean TRUE value if a suffix of the Text object matches the string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

end- String

`Returns:` bool_at

`*EQUALS_ANY` (text_t patset_name)

Results in Boolean TRUE value if the Text equals any of the strings that are bound to the patset or dataset named by the string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` bool_at

`*EQUALS_INDEX` (text_t patset_name)

Returns the numerical index of the matching string, if the Text equals any of the strings that are bound to the patset or dataset named by the string argument. Returns 0 if there is no match. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` num_at

`*EQ` (text_t s)

Results in Boolean TRUE value if the Text object matches the input argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*GET_SIGNED16` (`uint` n, endian_e endianness)

Get the 16-bit signed binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

endianness- Select little or big endian

`Returns:` num_at

`*GET_SIGNED32` (`uint` n, endian_e endianness)

Get the 32-bit signed binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

endianness- Select little or big endian

`Returns:` num_at

`*GET_SIGNED8` (`uint` n)

Get the 8-bit signed binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

`Returns:` num_at

`*GET_UNSIGNED16` (`uint` n, endian_e endianness)

Get the 16-bit unsigned binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

endianness- Select little or big endian

`Returns:` num_at

`*GET_UNSIGNED32` (`uint` n, endian_e endianness)

Get the 32-bit unsigned binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

endianness- Select little or big endian

`Returns:` unsigned_long_at

`*GET_UNSIGNED64` (`uint` n, endian_e endianness)

Get the 64-bit unsigned binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

endianness- Select little or big endian

`Returns:` unsigned_long_at

`*GET_UNSIGNED8` (`uint` n)

Get the 8-bit unsigned binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

`Returns:` num_at

`*GET_URLSET_METADATA` (text_t urlset_name)

Returns metadata value corresponding to pattern in the urlset. The matching is case-insensitive for domains, but case-sensitive for paths. If no pattern is matched within the urlset, the return value is a NULL string. For example:

- HTTP.REQ.HOST.APPEND(HTTP.REQ.URL).GET_URLSET_METADATA("urlset_forbidden") returns value when the combined domain and URL is looked up in the urlset whose name is "urlset_forbidden".

`Parameters` (expressions not allowed) `:`

urlset_name- urlset name

`Returns:` text_t

`*GE` (text_t s)

Results in Boolean TRUE value if the Text object is greater than or equal to the input argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*GRPC`

Interprets a text_t string as a Protocol Buffer (protocol_buffer_t type). Example: HTTP.REQ.BODY(1000).GRPC.STRING(1).EQ("bookname")

`Returns:` protocol_buffer_t

`*GT` (text_t s)

Results in Boolean TRUE value if the Text object is greater than the input argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*HASH`

Returns a positive 31 bit integer value computed by applying a proprietary NetScaler hash function to the selected text. This function is not case- sensitive and ignores whitespaces. For example, applying the HASH function to two strings "Ab c" and "abc" would produce the same value. This function should not be used for security purposes; use instead the DIGEST function with one of the standard digest methods.

`Returns:` num_at

`*HMAC` (text_t hmacKey)

Returns a byte sequence computed by applying the HMAC (Hash Message Authenticastion Code) function to the selected text using the configured HMAC key.

`Parameters` (expressions not allowed) `:`

hmacKey- indentifies the hmacKey object to provide the digest (hash) method and the key.

`Returns:` text_t

`*HMAC` (text_t hmacKey, binary_encoding_e out_encoding)

Returns a byte sequence computed by applying the HMAC (Hash Message Authenticastion Code) function to the selected text using the configured HMAC key .

`Parameters` (expressions not allowed) `:`

hmacKey- indentifies the hmacKey object to provide the digest (hash) method and the key.

out_encoding- specifies how the resulting HMAC is encoded.

`Returns:` text_t

`*HTML_XML_SAFE`

Apply XML safe transform and select text.

Converts '<', '>' and '&' in the input text to '<', '>' and '&' respectively; other characters in the input are not modified. This transform safeguards against XSS based attacks. This is a read only operation.

`Returns:` text_t

`*HTTP_HEADER_SAFE`

Apply Header safe transform and select text. Converts all new line ('\\n') characters present in the input text to '%0A' so that they can safely be used in HTTP headers. This transform safeguards against response-splitting attacks. This is a read only operation.

`Returns:` text_t

`*HTTP_URL_SAFE`

Apply URL safe transform and select text. Converts URL unsafe characters to corresponding '%xx' values and retains the rest. This is a read only operation.

Based on RFC2396, following are considered URL safe characters:

Alpha-numeric characters: a-z, A-Z, 0-9

Hyphen and underscore: "-", "_"

Dot: "."

Exclamation mark: "!"

Tilde: "~"

Asterix: "*"

Single quote: "'"

Open and close parentheses: "(", ")"

Semi-colon: ";"

Colon: ":"

At symbol: "@"

Question mark: "?"

Equals: "="

Dollar: "$"

Percent: "%"

Ampersand: "&"

Plus: "+"

Comma: ","

Forward slash: ".html"

The rest are converted to %XX encoding, 'XX' is the hex-based representation of the input character. If the requirement is to encode all but URL unreserved characters, please consider using URL_RESERVED_CHARS_SAFE method.

`Returns:` text_t

`*IS_BOOL_AT`

Results in Boolean TRUE value if the Text is of boolean type.

`Returns:` bool_at

`*IS_DOUBLE_AT`

Results in Boolean TRUE value if the Text is of double data type.

`Returns:` bool_at

`*IS_IPV6_AT`

Results in Boolean TRUE value if the Text is of IPv6 data type.

`Returns:` bool_at

`*IS_IPV6_SUBNET_AT`

Results in Boolean TRUE value if the Text is of IPv6 subnet data type.

`Returns:` bool_at

`*IS_IP_AT`

Results in Boolean TRUE value if the Text is of IPv4 data type.

`Returns:` bool_at

`*IS_MAC_ADDRESS_AT`

Results in Boolean TRUE value if the Text is of mac address data type.

`Returns:` bool_at

`*IS_NUM_AT`

Results in Boolean TRUE value if the Text is of number type.

`Returns:` bool_at

`*IS_NUM_AT` (num_format_e format)

Results in Boolean TRUE value if the Text is of number type with given input base.

`Parameters` (expressions not allowed) `:`

format- number format

`Returns:` bool_at

`*IS_STRINGMAP_KEY` (text_t string_map_name)

Returns true if the string that it operates on is present in the string map. Text mode IGNORECASE, NOIGNORECASE - controls whether key lookup in string map is case sensitive or not. For example:

- HTTP.REQ.URL.IS_STRINGMAP_KEY("url_stringmap") returns true if value of HTTP.REQ.URL is present as key in the string map whose name is "url_stringmap".
- HTTP.REQ.URL.SET_TEXT_MODE(IGNORECASE). IS_STRINGMAP_KEY("url_stringmap") returns true if value of HTTP.REQ.URL is present as key in the string map whose name is "url_stringmap". Key lookup in this case is done case-insensitively.

`Parameters` (expressions not allowed) `:`

string_map_name- identifies the string map.

`Returns:` bool_at

`*IS_TIME_AT`

Results in Boolean TRUE if the Text follows any of the standard time formats given below, otherwise false. Tue, 05 Nov 1994 08:12:31 GMT RFC822 Tuesday, 05-Nov-94 08:12:31 GMT RFC850 Tue Nov 4 08:12:31 1994 asctime

`Returns:` bool_at

`*IS_UNSIGNED_LONG_AT`

Results in Boolean TRUE value if the Text is of unsigned long data type.

`Returns:` bool_at

`*IS_UNSIGNED_LONG_AT` (num_format_e format)

Results in Boolean TRUE value if the Text is of unsigned long data type with given input base.

`Parameters` (expressions not allowed) `:`

format- number format

`Returns:` bool_at

`*JWT_VERIFY_CERTKEY` (text_t certkey_name)

Verifies the signature on the input JSON Web Token (JWT), using the RSA public key in the X.509 certificate in the specified certkey object. The token has the format HEADER.PAYLOAD.SIGNATURE where

- HEADER is a base64-encoded JSON structure indicating a signature algorithm and token type, e.g.'{"alg":"RS256","typ":"JWT"}'
- PAYLOAD is a base64-encoded JSON structure with asserted claims, e.g. '{"loggedInAs":"admin","iat":1422779638}'
- SIGNATURE is the base64-encoded bytes for the signature on HEADER.PAYLOAD.

Returns true if the signature is verified for the header and payload using the specified public key; false if the signature is not verified

`Parameters``:`

certkey_name- identifies the certkey object containing an X.509 certificate holding the RSA public key. Results in an Undef error if the certkey object does not exist or does not contain an X.509 certificate with an RSA public key, if the token is not correctly formatted, or if the verification operation cannot complete.

`Returns:` bool_at

`*JWT_VERIFY_XML` (text_t xml_pkey)

Verifies the signature on the input JSON Web Token (JWT), using the RSA public key supplied by the specified XML element. The token has the format HEADER.PAYLOAD.SIGNATURE where

- HEADER is a base64-encoded JSON structure indicating a signature algorithm and token type, e.g.'{"alg":"RS256","typ":"JWT"}'
- PAYLOAD is a base64-encoded JSON structure with asserted claims, e.g. '{"loggedInAs":"admin","iat":1422779638}'
- SIGNATURE is the base64-encoded bytes for the signature on HEADER.PAYLOAD.

Returns true if the signature is verified for the header and payload using the specified public key; false if the signature is not verified

`Parameters``:`

xml_pkey- an expression that supplies an <RSAKeyValue> element with the public key. Results in an Undef error if the XML element is invalid or does not correctly specify an RSA public key, if the token is not correctly formatted, or if the verification operation cannot complete.

`Returns:` bool_at

`*LE` (text_t s)

Results in Boolean TRUE value if the Text object is less than or equal to the input argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*LOCATION_LONG`

Get the location qualifier from CLIENT.IP.SRC.LOCATION.GET(n) (ISO short name) and then convert it to human readable long name. This conversion is valid only for country names. Correct Country qualifier value (number) in GET(n) is left up to the user as qualifiers are user configurable. Expression example: CLIENT.IP.SRC.LOCATION.GET(1).LOCATION_LONG For example: Data from each expression CLIENT.IP.SRC.LOCATION: NA.US.California.SantaClara.*.* CLIENT.IP.SRC.LOCATION.GET(1): US CLIENT.IP.SRC.LOCATION.GET(1).LOCATION_LONG: United States

`Returns:` text_t

`*LT` (text_t s)

Results in Boolean TRUE value if the Text object is less than the input argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*MAP_STRING_DEFAULT_TO_KEY` (text_t string_map_name)

Returns the value corresponding to the key in the string map. This is similar to the MAP_STRING method, but if the key is not present then instead of returning a null string, it returns the key itself. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

string_map_name- identifies the string map.

`Returns:` text_t

`*MAP_STRING` (text_t string_map_name)

Returns value corresponding to key in the string map. Key is the string that it is given as input. Text mode IGNORECASE, NOIGNORECASE - controls whether key lookup in string map is case sensitive or not. For example:

- HTTP.REQ.URL.MAP_STRING("url_stringmap") returns value when the value of HTTP.REQ.URL is used as key in the string map whose name is "url_stringmap".
- HTTP.REQ.URL.SET_TEXT_MODE(IGNORECASE). MAP_STRING("url_stringmap") returns value when the value of HTTP.REQ.URL is used as key in the string map whose name is "url_stringmap". Key lookup in this case is done case-insensitively.

`Parameters` (expressions not allowed) `:`

string_map_name- identifies the string map.

`Returns:` text_t

`*MARK_SAFE`

Mark the PIXL expression safe without applying any safe transform.

`Returns:` text_t

`*MAX` (text_t s)

Compares the string argument with the current string and returns the max string. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*MIN` (text_t s)

Compares the string argument with the current string and returns the min string. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*NE` (text_t s)

Results in Boolean TRUE value if the Text object is not equal to the input argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*NORMALIZE_URL`

Normalize URL. Normalizes a URL by doing "percent" decoding. See the description for URLENCODED in the SET_TEXT_MODE function. This performs the equivalent of SET_TEXT_MODE(URLENCODED).DECODE_USING_TEXT_MODE, except that it does not change the value of the current text mode.

`Returns:` text_t

`*PKEY_ENCRYPT_PEM_NO_PADDING` (text_t pem_pkey)

Encrypts the input text using the RSA public key provided by the PEM string and RSA_NO_PADDING padding method. The input text to be encrypted cannot be longer than the public key length minus 11 bytes for padding. For example, for a 1024-bit (128 byte) key, the input text cannot be longer than 128 - 11 = 117 bytes. An Undef error will occur if the input text is too long. A null input will also cause an Undef error. Returns the (unencoded binary) encrypted text, which is typically base-64 encoded for use in a message.

`Parameters``:`

pem_pkey- a text expression that supplies a RSA public key in the PEM format. If the text value is not a valid PEM RSA PUBLIC KEY encoding, an Undef error will occur. Example (a 1024-bit public key):

```
"-----BEGIN RSA PUBLIC KEY-----" +

"MIGJAoGBAKl5vgQEj73Kxp+9yn1v5gPR1pnc4oLM2a0kaWwBOsB6rzCIy6znwnvw" +

"CY1xRvQhRlJSAyJbloL7wZFIJ2FOR8Cz+8ZQWXU2syG+udi4EnWqLgFYowF9zK+o" +

"79az597eNPAjsHZ/C2oL/+6qY5a/f1z8bQPrHC4GpFfAEJhh/+NnAgMBAAE=" +

"-----END RSA PUBLIC KEY-----"
```

`Returns:` text_t

`*PKEY_ENCRYPT_PEM` (text_t pem_pkey)

Encrypts the input text using the RSA public key provided by the PEM string and the RSA_PKCS1_PADDING padding method. The input text to be encrypted cannot be longer than the public key length minus 11 bytes for padding. For example, for a 1024-bit (128 byte) key, the input text cannot be longer than 128 - 11 = 117 bytes. An Undef error will occur if the input text is too long. A null input will also cause an Undef error. Returns the (unencoded binary) encrypted text, which is typically base-64 encoded for use in a message.

`Parameters``:`

pem_pkey- a text expression that supplies a RSA public key in the PEM format. If the text value is not a valid PEM RSA PUBLIC KEY encoding, an Undef error will occur. Example (a 1024-bit public key):

```
"-----BEGIN RSA PUBLIC KEY-----" +

"MIGJAoGBAKl5vgQEj73Kxp+9yn1v5gPR1pnc4oLM2a0kaWwBOsB6rzCIy6znwnvw" +

"CY1xRvQhRlJSAyJbloL7wZFIJ2FOR8Cz+8ZQWXU2syG+udi4EnWqLgFYowF9zK+o" +

"79az597eNPAjsHZ/C2oL/+6qY5a/f1z8bQPrHC4GpFfAEJhh/+NnAgMBAAE=" +

"-----END RSA PUBLIC KEY-----"
```

`Returns:` text_t

`*PKEY_SIGN_CERTKEY` (text_t certkey_name)

Generates a binary digital signature using the SHA-256 message digest function and an RSA private key from the specified SSL certKey object.

`Parameters``:`

certkey_name- identifies the configured certKey object. Results in an Undef error if the certkey object does not exist or does not contain an RSA private key, or if the signing operation cannot complete.

`Returns:` text_t

`*PKEY_SIGN_XML` (text_t xml_pkey)

Generates a binary digital signature using the SHA-256 message digest function and an RSA private key from the specified XML element.

`Parameters``:`

xml_pkey- an expression that supplies an <RSAKeyValue> element with the private key. Example: <RSAKeyValue> <Modulus>qXm+BASPvcrGn73KfW/
mA9HWmdzigszZrSRpbAE6wHqvMIjLrOfCe/
AJjXFG9CFGUlIDIluWgvvBkUgnYU5HwLP7xlBZdTazIb652LgSdaouAVijAX3Mr6jv1rPn3t408COwdn8Lagv/
7qpjlr9/XPxtA+scLgakV8AQmGH/42c=</Modulus> <Exponent>AQAB</Exponent>"zNjysxcIJV/
J9cTpIgPp2/x1IXHT5GTH8OMuNad0qtRSLjU1QYUmmkm9QcJJAN+7h8FEXWGabySUzBrHj/
IEbw=="
<DP>QavUDQLLQpnPJXtVAo6CYhxOMCd68mwTxYKKNLjmC0pd54SFHllTLPE1FZU5EjK6q3nCeijonpfH+XX
DP> <DQ>EiXOKouJzzXTQJC3TqomF7Uf81yQNxWumOqnd11kepXgyfMwyqMvLlAGEkNSEF/
Bz18R3Wv+MIZ/IC3nLBt2xQ==</DQ>
<InverseQ>ocuCmz36CP+N2aGqxaU+BKD5+3RLgRq9LFhULEz2jKx0iV9r76jsAxn3sLcTYYO9eqRPy2cz74AU
nw==</InverseQ> <D>fTBD773a3GzcmgVdfZlaBLpN1ux2mf5uUVrTUQf7eVFm9egm4/
tzC5A9zjC+I/oscwTH8epL3UfRLdtp05Q6pWfJBXEnGo0QmOFFBK4pLx/
5JJpPGZ69ovDFEVOUHyiCfKE/g97T4WX3us0nFe1272zwGlHarM1YYwvfeE08UdE=</D> </
RSAKeyValue> Results in an Undef error if the XML element is invalid or does not correctly specify an RSA private key, or if the signing operation cannot complete.

`Returns:` text_t

`*PKEY_VERIFY_CERTKEY` (text_t certkey_name, text_t signature)

Verifies if the input text matches the specified signature generated using the SHA-256 messge digest function and the RSA private key associated with the specified RSA public key in the X.509 certificate in the specified certKey object. Returns true if the signature is verified, false otherwise.

`Parameters``:`

certkey_name- identifies the certkey object containing an X.509 certificate holding the RSA public key.

signature- the binary signature. Results in an Undef error if the certkey object does not exist or does not contain an X.509 certificate with an RSA public key, or if the verification operation cannot complete.

`Returns:` bool_at

`*PKEY_VERIFY_XML` (text_t xml_pkey, text_t signature)

Verifies if the input text matches the specified signature generated using the SHA-256 messge digest function and the RSA private key associated with the RSA public key supplied by the specified XML element. Returns true if the signature is verified, false otherwise.

`Parameters``:`

xml_pkey- an expression that supplies an <RSAKeyVAlue> element with the public key. Example: <RSAKeyValue> <Modulus>qXm+BASPvcrGn73KfW/mA9HWmdzigszZrSRpbAE6wHqvMIjLrOfCe/AJjXFG9CFGUlIDIluWgvvBkUgnYU5HwLP7xlBZdTazIb652LgSdaouAVijAX3Mr6jv1rPn3t408COwdn8Lagv/7qpjlr9/XPxtA+scLgakV8AQmGH/42c=</Modulus> <Exponent>AQAB</Exponent> </RSAKeyValue>

signature- the binary signature. Results in an Undef error if the XML element is invalid or does not correctly specify an RSA public key, or if the verification operation cannot complete.

`Returns:` bool_at

`*PREFIX` (`char` c, `uint` i)

Select a prefix of the Text. The selected prefix is the longest prefix that has at most Count (2nd argument) occurrences of character in the 1st argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

c- Character

i- Count

`Returns:` text_t

`*PREFIX` (`uint` i)

Select a prefix of the Text. The length of the prefix is equal to the number in the argument. If there aren't enough characters in the Text object then the entire Text is selected.

`Parameters``:`

i- Prefix Length

`Returns:` text_t

`*REGEX_MATCH` (`re` regex)

Returns TRUE if and only if the text contains at least one match of the regular expression argument. The match may occur anywhere within the text - if you wish to "anchor" this, use "\^" at the start of the regex and/or "$" at the end of the regex.

The regular expression has to be of the format: `re<delimiter>regular expression<same delimiter>`

The regular expression cannot be bigger than 1499 characters.

The regular expression should be acceptable by the PCRE regular expression library. Look at http://www.pcre.org/pcre.txt for documentation on the regular expression syntax. In particular, look at the pcrepattern man page.

There are some differences in the allowed syntax w.r.t PCRE syntax. Backreferences are not allowed. It is recommended not to use recursive regular expressions. The dot metacharacter matches newlines also. Unicode is not supported. SET_TEXT_MODE(IGNORECASE) overrides the (?i) internal option specified in the regular expression.

The PCRE library configuration can be seen in the system log, after executing 'nsapimgr -B" call ns_pixl_regex_show_config()"' at the shell prompt.

Some examples:

- HTTP.REQ.HOSTNAME.REGEX_MATCH(re/\[\[:alpha:\]\]+(abc){2,3}/)
- HTTP.REQ.URL.SET_TEXT_MODE(URLENCODED).REGEX_MATCH(re#(a*b+c*)#)

- HTTP.REQ.URL.REGEX_MATCH(re/a(?i)b/) matches ab and aB
- HTTP.REQ.URL.SET_TEXT_MODE(IGNORECASE).REGEX_MATCH(re/ab/) matches ab, aB, Ab and AB
- HTTP.REQ.BODY.REGEX_MATCH(re/(?ixm) (\^ab (.*) cd$) /) does a case-insensitive, multiline match where the dot metacharacter matches newline also. The regex itself can contain whitespace which will be ignored during the matching (x - extended regex).

This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

regex- Regular Expression

`Returns:` bool_at

`*REGEX_REPLACE` (`re` regex, text_t replacement, replacemode_e mode)

Selects the text that matches the given regular expression argument and replaces it with the the text given in the second argument. The third argument specifies whether the first match is only replaced when multiple matches occur in the text or all matches are replaced. The match may occur anywhere within the text - if you wish to "anchor" this, use "\^" at the start of the regex and/or "$" at the end of the regex. When the regular expression does not match the given string then the same string is returned.

For example: HTTP.RES.BODY(999).REGEX_REPLACE(re!\\bpassword:\\s*\\b!, "password: ***", ALL) will replace all occurrences of "password:" with "password: ***" This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

regex- Regular Expression

replacement- String to replace the match

mode- Mode of replacement

`Returns:` text_t

`*REGEX_SELECT` (`re` regex)

Selects the text that matches the given regular expression argument. The first match is returned when multiple matches occur in the text. The match may occur anywhere within the text - if you

wish to "anchor" this, use "\^" at the start of the regex and/or "$" at the end of the regex. When the regular expression does not match the given string, a Text object of length of 0 is returned.

For example: HTTP.REQ.HEADER("via").REGEX_SELECT(re!NS-CACHE-\\d\\.\\d:\\s*\\d{1,3}!) will select "NS-CACHE-7.0: 70" This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

regex- Regular Expression

`Returns:` text_t

`*REPEAT` (`uint` i)

Produces a string which contains 'i' sequential copies of the input string.

`Parameters``:`

i- the number of times to repeat the string (0 or more)

`Returns:` text_t

`*SET_CHAR_SET` (charset_e charset)

Set the character set to use for subsequent functions that use text.

`Parameters` (expressions not allowed) `:`

charset- Character Set

`Returns:` avp_t

`*SET_TEXT_MODE` (textmode_e mode)

The mode setting of a Text object controls the behavior of many Text operations. The Text mode settings may also control the behavior of some operations in objects (like List) that build upon the Text object. IGNORECASE, NOIGNORECASE - controls whether string comparison is case sensitive or not. URLENCODED - If set then all Text operations are carried out after translating all %HH or %uHHHH encodings in the underlying byte stream. 1. %HH will be translated to the character Y where HH denotes the ascii value of character Y in hexadecimal. For example, the encoded text "http%3a/.html" will be decoded to "http:/.html" 2. %uWWHH will be translated to the character sequence YZ where WW denotes the ascii value of character Y in hexadecimal and HH denotes the ascii value of character Z in hexadecimal. For example, the encoded text

"http%u3a2f.html" and "http%u003a/.html" will both be decoded to"http:/.html" NOURLENCODED - Indicates that no percent encodings are present in the Text object. No percent decoding will be performed on the Text object. PLUS_AS_SPACE - If set then all Text operations are carried out after converting occurrences of the plus character to whitespace. For example, the text "hello+world" will be decoded to "hello world" NO_PLUS_AS_SPACE - If set, then the plus character will not be converted to whitespace in the Text object. BACKSLASH_ENCODED - If set, then all Text operations are carried out after performing the following operations: 1. \\XXX will be translated to the character Y where XXX denotes the ascii value of character Y in octal. The valid range of octal values for this type of encoding is \\0 to \\377. For example, the encoded text "http\ \72/.html" and "http\\072/.html" will both be decoded to "http:/.html" 2. \\xHH will be translated to the character Y where HH denotes the ascii value of character Y in hexadecimal. For example, the encoded text "http\\x3a/.html" will be decoded to "http:/.html" 3. \\\\uWWXX will be translated to the character sequence YZ where WW denotes the ascii value of character Y in hexadecimal and XX denotes the ascii value of character Z in hexadecimal. For example, the encoded text "http%u3a2f.html" and "http%u003a/.html" will both be decoded to"http:/.html" 4. Occurences of "\ \b", "\\n", "\\t", "\\f" and "\\r" are translated to the corresponding ascii characters. NO_BACKSLASH_ENCODED - If set, then backslash decoding will not be performed on the Text object. BAD_ENCODE_RAISE_UNDEF - If set, then UNDEF is raised if either the URLENCODED or BACKSLASH_ENCODED mode is set and a bad encoding corresponding to the specified encoding mode is encountered. NO_BAD_ENCODE_RAISE_UNDEF - If set, then UNDEF will not be raised when a bad encoding is encountered in the Text object. The Text operations operate on characters (as opposed to operating on bytes). By default a single byte represents a character using the ASCII encoding. But if URLENCODED mode is set then 3 bytes may represent a character. A PREFIX(3) operation will select the first 3 characters in the Text object. That means it may select up to 9 bytes for URLENCODED Text object. In the case of multibyte decodings as a result of %uXXXX or \\\\uXXXX, Text operations which attempt to treat the multiple decoded bytes as distinct characters are not allowed.

`Parameters` (expressions not allowed) `:`

mode- Text Mode

`Returns:` avp_t

`*SKIP` (`char` c, `uint` i)

Select the Text after skipping over a prefix of the current Text. The skipped over prefix is the longest prefix that has at most Count (2nd argument) occurrences of character in the 1st argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

c- Character

i- Count

`Returns:` text_t

`*SKIP` (`uint` i)

Select the Text after skipping over a prefix in the current Text. The length of the prefix is equal to the number in the argument. If there aren't enough characters in the Text object then the entire Text is skipped over.

`Parameters` (expressions not allowed) `:`

i- Prefix Length

`Returns:` text_t

`*STARTSWITH_ANY` (text_t patset_name)

Results in Boolean TRUE value if the Text starts with any of the strings that are bound to the patset or dataset named by the string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` bool_at

`*STARTSWITH_INDEX` (text_t patset_name)

Returns the numerical index of the matching string, if the Text starts with any of the strings that are bound to the patset or dataset named by the string argument. Returns 0 if there is no match. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` num_at

`*STARTSWITH` (text_t start)

Results in Boolean TRUE value if a prefix of the Text object matches the string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

start- String

`Returns:` bool_at

`*STRIP_CHARS` (text_t s)

From the selected text remove the characters specified in the string.

For example: Say the selected text is / "foo.xyz=bar" /. Then on executing STRIP_CHARS('.=') or STRIP_CHARS('..=') the selected text will become /fooxyzbar /. Note that repeating character has same effect as it would be if it present only once. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*STRIP_END_CHARS` (text_t s)

Selects the Text after stripping off characters in the end of the current Text object.

For example: Say the selected text is / "foo.xyz=bar" /. Then on executing STRIP_END_CHARS('ar') the selected text will become /foo.xyz=b /. Note that repeating character has same effect as it would be if it present only once. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*STRIP_END_WS`

Selects the Text after stripping off white space in the end of the current Text object.

`Returns:` text_t

`*STRIP_START_CHARS` (text_t s)

Selects the Text after stripping off characters in the beginning of the current Text object.

For example: Say the selected text is / "foo.xyz=bar" /. Then on executing STRIP_START_CHARS('of') the selected text will become /.xyz=bar /. Note that repeating character has same effect as it would be if it present only once. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*STRIP_START_WS`

Selects the Text after stripping off white space in the beginning of the current Text object.

`Returns:` text_t

`*SUBSTR_ANY` (text_t patset_name)

Select any one sub-string that matches any string in the given patset or dataset. The patset cannot have strings longer than 255 characters. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` text_t

`*SUBSTR` (`uint` start, `uint` len)

Select the Text object of the given length at the given offset. Offset it 0 based. If there aren't enough characters after the offset then all the remaining characters are selected.

`Parameters``:`

start- Offset

len- Length

`Returns:` text_t

`*SUBSTR` (text_t s)

Select the first Text object that matches the input string argument. The input string cannot be bigger than 255 characters. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*SUFFIX` (`char` c, `uint` i)

Select a suffix of the Text. The selected suffix is the longest possible suffix containing at most Count (2nd arg) occurrences of the character in the 1st argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

c- Character

i- Count

`Returns:` text_t

`*SUFFIX` (`uint` i)

Select a suffix of the Text. The length of the suffix is equal to the number in the argument. If there aren't enough characters in the Text object then the entire Text is selected.

`Parameters``:`

i- Suffix Length

`Returns:` text_t

`*TO_LOWER`

Converts the selected text to lower case.

For example, the string "ABCd" is converted to "abcd"

`Returns:` text_t

`*TO_UPPER`

Converts the selected text to upper case.

For example, the string "abcD" is converted to "ABCD"

`Returns:` text_t

`*TRUNCATE` (`char` c, `uint` i)

Select the Text after truncating a suffix from the current Text object. The truncated suffix is the longest possible suffix containing at most Count (2nd arg) occurrences of the character in the 1st argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

c- Character

i- Count

`Returns:` text_t

`*TRUNCATE` (`uint` i)

Select the Text after truncating a suffix of the Text. The length of the suffix truncated is equal to the number in the argument. If there aren't enough characters in the Text then then all the characters are truncated.

`Parameters``:`

i- Suffix Length

`Returns:` text_t

`*TYPECAST_AVP_T`

Convert text_t to avp_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (avp_t : Operations that can be performed on the returned AVPs.

`Note:` An AVP can have multiple instances in a Diameter message. However, the system can access only the first 16 instances.

`Example:`

- To get the first value of AVP code 266 from a request, use: DIAMETER.REQ.AVP(266).VALUE(0).

- To get the fourth value of AVP code 266 from a request, use: DIAMETER.REQ.AVP(266).VALUE(3).
- To check if AVP code 1000 in the response has the vendor-specific bit set, use: DIAMETER.RES.AVP(1000).IS_VENDOR_SPECIFIC.

)

`Returns:` avp_t

`*TYPECAST_AVP_UNUM_T`

Convert text_t to avp_unum_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (avp_unum_t : In Diameter AVP based expressions can be written as DIAMETER.REQ.AVP(<avpcode>). For example Auth-Application-Id AVP (AVP code 258) can be extracted as DIAMETER.REQ.AVP(258) For few of the important AVPs we provide aliases. For example this AVP based expression can also be written as DIAMETER.REQ.AUTH_APPLICATION_ID. This expression returns either a object of class avp_t or returns a numerical value (object of class unsigned_long_at). The numerical value for this object is derived from the value in first instance of the AVP.)

`Returns:` avp_unum_t

`*TYPECAST_BOOL_AT`

Convert text_t to bool_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (bool_at : Boolean Operations)

`Returns:` bool_at

`*TYPECAST_COOKIE_T`

Convert text_t to cookie_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (cookie_t : The HTTP Cookie type provides operations for a cookie as it appears in the Set-Cookie and Set-Cookie2 header. In this type the Name-Value List operations are also available. The first delimiter is = and the element delimiter is ;. Multiple consecutive ; are treated as one. (Same as applying the method IGNORE_EMPTY_ELEMENTS on a Name-Value List.) You can use the Name-value List operations to access cookie attributes. The name comparison for all list operations is case insensitive. In this type Text operations are also available. Each cookie begins with a COOKIE_NAME=COOKIE_VALUE pair followed by zero or more semi-colon separated attribute-value pairs. If an attribute appears more than once in a cookie, the value associated with the first appearance of the attribute is returned.

Format Cookie: Cookie1=Value;Version=decimal;Value;Domain=Value;Path=Value)

`Returns:` cookie_t

`*TYPECAST_DIAMETER_FLAG_T`

Convert text_t to diameter_flag_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (diameter_flag_t : Provides operation to treat the underlying 1 byte as set of bit flags. then set/unset/test/reset_all operations can be done on flag)

`Returns:` diameter_flag_t

`*TYPECAST_DNS_DOMAINNAME_T`

Convert text_t to dns_domainname_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (dns_domainname_t : This object provides operations for parsing the DNS domain name as it appears at various places in the DNS data. The format is abc.foo.com.)

`Returns:` dns_domainname_t

`*TYPECAST_DNS_FLAG_T`

Convert text_t to dns_flag_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (dns_flag_t : Provides operations to test/set/unset a flag in dns header.)

`Returns:` dns_flag_t

`*TYPECAST_DOUBLE_AT`

Convert text_t to double_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_at : Double Value)

`Returns:` double_at

`*TYPECAST_DOUBLE_T` (double_format_e format)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one

or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error.)

`Parameters` (expressions not allowed) `:`

format- Format

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, double_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, ip_address_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, num_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, time_local_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, time_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one

or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, unsigned_long_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_HTTP_CACHE_CONTROL_T`

Convert text_t to http_cache_control_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_cache_control_t : This object provides for the ability to work on HTTP Cache-Control headers. The name comparison for all list operations is case insensitive.)

`Returns:` http_cache_control_t

`*TYPECAST_HTTP_CONTENT_LENGTH_T`

Convert text_t to http_content_length_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_content_length_t : The HTTP.REQ.CONTENT_LENGTH or HTTP.RES.CONTENT_LENGTH object can be treated as a

HTTP Header or as a Number. The numerical value for this object is derived from the value in the last instance of the Content-Length header.)

`Returns:` http_content_length_t

`*TYPECAST_HTTP_COOKIE_T`

Convert text_t to http_cookie_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_cookie_t : This object provides operations for parsing the HTTP cookie header. The name-value pair is derived from the value in the last instance of Cookie header. The format is Cookie : name0=value0; name1=value1; An HTTP Cookie header can have multiple occurrences. COUNT will return a Number containing how many headers of the current type exist. The name comparison for all list operations is case insensitive. The system does not keep track of more than 15 HTTP headers. The result will be undefined if there are more than 15 instances of the header.)

`Returns:` http_cookie_t

`*TYPECAST_HTTP_DATE_T`

Convert text_t to http_date_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_date_t : The HTTP.REQ.DATE or HTTP.RES.DATE object can be treated as a HTTP header or a Time object. The Time value is derived from the value in the last instance of the Date header. The date formats supported are RFC 822 (updated by RFC 1123), RFC 1036 (obsoletes RFC850) and ANSI C asctime() formats.)

`Returns:` http_date_t

`*TYPECAST_HTTP_HEADER_T` (text_t name)

Convert text_t to http_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_header_t : When typecasting a Text object to HTTP Header a header name must be provided.For example: HTTP.REQ.HEADER("MyHdr").TYPECAST_HTTP_HEADER_T("InHdr"))

`Parameters` (expressions not allowed) `:`

name- Header Name

`Returns:` http_header_t

`*TYPECAST_HTTP_HOSTNAME_T`

Convert text_t to http_hostname_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_hostname_t : This object provides operations for parsing the HTTP hostname as it appears at various places in the HTTP protocol data. The format is abc.foo.com:8080.)

`Returns:` http_hostname_t

`*TYPECAST_HTTP_METHOD_T`

Convert text_t to http_method_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_method_t : This object provides Text operations and HTTP Request Method Enum operations on the HTTP request method.)

`Returns:` http_method_t

`*TYPECAST_HTTP_SET_COOKIE_T`

Convert text_t to http_set_cookie_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_set_cookie_t : HTTP.RES.SET_COOKIE provides operations for parsing and operating on the SET-COOKIE header that is present in the HTTP response. HTTP Set-Cookie header supports Text and HTTP Header operations. For most Text operations the value in the last Set-Cookie header is selected. HTTP Set-Cookie header also supports special operations to extract cookies from the response. It is assumed that there will be only one cookie in a Set-Cookie header.)

`Returns:` http_set_cookie_t

`*TYPECAST_HTTP_URL_T`

Convert text_t to http_url_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_url_t : HTTP.REQ.URL provides operations for parsing and operating on the URL that is present in the first line of the HTTP request header. The supported format is \[<protocol>://<hostname>\]<path>?<query>. The Text object backing a HTTP URL object has the Text Mode set to URLENCODED by default.)

`Returns:` http_url_t

`*TYPECAST_HTTP_VERSION_T`

Convert text_t to http_version_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_version_t : HTTP.REQ.VERSION or HTTP.RES.VERSION provide operations to extract HTTP version information.)

`Returns:` http_version_t

`*TYPECAST_IPV6_ADDRESS_AT`

Convert text_t to ipv6_address_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ipv6_address_at : Provides operations for the 128-bit IPv6 address value. Some general information regarding IPv6 expressions: IPv6 PIXL expressions can be combined with other PIXL expressions using the '+' operator. The output is expected to be the concatenation of the string representations of the individual PIXL expressions. No other operator other than '+' is expected to work when any of the operands is an IPv6 PIXL expression. Also, IPv6 PIXL expressions can be combined with any other type of PIXL expression except a PIXL expression that produces a bool result. In other words, if A and/or B are two IPv6 addresses, A+B should result in the string AB. When one of A or B is an IPv6 address, the other can only be a number or a string and not a boolean. Further, when A and/or B is an IPv6 address, the only operator allowed between them is '+'.

Example: Let the client source IPv6 address be ABCD:1234::ABCD. Let the server destination IPv4 address be 10.100.10.100. Then the expression CLIENT.IPV6.SRC + SERVER.IP.DST should produce the output "ABCD:1234::ABCD10.100.10.100". Similarly, CLIENT.IPV6.SRC + 5 should produce the result ABCD:1234::ABCD5)

`Returns:` ipv6_address_at

`*TYPECAST_IPV6_ADDRESS_T`

Convert text_t to ipv6_address_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ipv6_address_t : This object represents an IPv6 address present in the 1000:1001:CD10:0000:0000:89AB:4567:CDEF format.)

`Returns:` ipv6_address_t

`*TYPECAST_IPV6_SUBNET_AT`

Convert text_t to ipv6_subnet_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ipv6_subnet_at : Provides operations for the integral IPv6 subnet address value.)

`Returns:` ipv6_subnet_at

`*TYPECAST_IPV6_SUBNET_T`

Convert text_t to ipv6_subnet_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ipv6_subnet_t : This object represents an IPv6 subnet address present in the 1000:1001:CD10:0000:0000:89AB:4567:CDEF/64 format.)

`Returns:` ipv6_subnet_t

`*TYPECAST_IP_ADDRESS_AT`

Convert text_t to ip_address_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ip_address_at : Provides operations for the 32-bit integral IP address value.)

`Returns:` ip_address_at

`*TYPECAST_IP_ADDRESS_T`

Convert text_t to ip_address_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ip_address_t : Represents an IP address present in the 10.100.200.1 format.)

`Returns:` ip_address_t

`*TYPECAST_IP_OPTIONS_T`

Convert text_t to ip_options_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ip_options_t : IP protocol options)

`Returns:` ip_options_t

`*TYPECAST_IP_OPTIONS_TYPE_T`

Convert text_t to ip_options_type_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ip_options_type_t : IP Options Type)

`Returns:` ip_options_type_t

`*TYPECAST_IP_TOS_T`

Convert text_t to ip_tos_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ip_tos_t : Provides operations to TOS field in IP header.)

`Returns:` ip_tos_t

`*TYPECAST_LIST_T` (`char` sep)

Convert text_t to list_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (list_t : The character separator has to be provided when typecasting a textual context to list type. The current text mode has no effect on the character separator. For example if the current text mode is IGNORECASE and the separator is p then P will not be treated as a separator.)

`Parameters` (expressions not allowed) `:`

sep- Separator

`Returns:` list_t

`*TYPECAST_MAC_ADDRESS_AT`

Convert text_t to mac_address_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (mac_address_at : Provides operations for the 48-bit MAC address value.)

`Returns:` mac_address_at

`*TYPECAST_MAC_ADDRESS_T`

Convert text_t to mac_address_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (mac_address_t : Represents a MAC address present in the 12:34:56:78:9a:bc format.)

`Returns:` mac_address_t

`*TYPECAST_NUM_AT`

Convert text_t to num_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (num_at : Number Value)

`Returns:` num_at

`*TYPECAST_NUM_T` (num_format_e format)

Convert text_t to num_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (num_t : Treat the underlying text as a Number in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and

HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error.)

`Parameters` (expressions not allowed) `:`

format- Format

`Returns:` num_t

`*TYPECAST_NUM_T` (num_format_e format, num_at default_value)

Convert text_t to num_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (num_t : Treat the underlying text as a Number in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` num_t

`*TYPECAST_NVLIST_T` (`char` sep1, `char` sep2)

Convert text_t to nvlist_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (nvlist_t : Two character delimiters have to be provided when typecasting a Text object to a Name-Value List. The first delimited separates the name from the value. The second delimiter separates list items. For example typecast_nvlist_t('=', '&') handles a URL query string. The Text Mode has no effect on the character delimiters. For example if the current text mode is IGNORECASE and a delimiter is p then P will not be treated as a delimiter.)

`Parameters` (expressions not allowed) `:`

sep1- delimiter1

sep2- delimiter2

`Returns:` nvlist_t

`*TYPECAST_NVLIST_T` (`char` sep1, `char` sep2, `char` quote)

Convert text_t to nvlist_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (nvlist_t : Two character delimiters and quote-character have to be provided when typecasting a Text object to a Name-Value List that supports quote-character. The first delimited separates the name from the value. The second delimiter separates list items. The third value specifies the quote character. For example typecast_nvlist_t('=', ';', "") handles a name-value list separated by semi-colons that allows quoting. The quote-character specifies that the value can occur within the quotes and the delimiters within the quote-characters should not be taken into account. The Text Mode has no effect on the character delimiters. For example if the current text mode is IGNORECASE and a delimiter is p then P will not be treated as a delimiter.)

`Parameters` (expressions not allowed) `:`

sep1- delimiter1

sep2- delimiter2

quote- quote-character.

`Returns:` nvlist_t

`*TYPECAST_PROTOCOL_BUFFER_T`

Convert text_t to protocol_buffer_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (protocol_buffer_t : gRPC Protocol Buffers interface)

`Returns:` protocol_buffer_t

`*TYPECAST_RADIUS_AVP_T`

Convert text_t to radius_avp_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (radius_avp_t : Operations that can be performed on the returned AVPs.

`Note:` An AVP can have multiple instances in a radius message. However, the system can access only the first 16 instances.

`Example:`

- To get the first value of AVP code 26 from a request, use: radius.REQ.AVP(26).VALUE(0).
- To get the fourth value of AVP code 26 from a request, use: radius.REQ.AVP(26).VALUE(3).

)

`Returns:` radius_avp_t

`*TYPECAST_RADIUS_AVP_VALUE_T`

Convert text_t to radius_avp_value_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (radius_avp_value_t : Provides operations to typecast RADIUS AVP value to Integer value or IP Address.)

`Returns:` radius_avp_value_t

`*TYPECAST_SEQ_TEXT_T`

Convert text_t to seq_text_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (seq_text_t : Represents the Text Sequence class.)

`Returns:` seq_text_t

`*TYPECAST_SERVICEPATH_T`

Convert text_t to servicepath_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (servicepath_t : Operations that can be performed on the service path.

`Example:`

- To get the name of the service path applicable to current subscriber, use: SUBSCRIBER.SERVICEPATH
- To determine If the service function is the next in the service path applicable to scubscriber, use: SUBSCRIBER.SERVICEPATH.IS_NEXT().

)

`Returns:` servicepath_t

`*TYPECAST_SIP_CALLID_HEADER_T`

Convert text_t to sip_callid_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_callid_header_t : This object provides operations for parsing the SIP callid header.)

`Returns:` sip_callid_header_t

`*TYPECAST_SIP_CONTENT_LENGTH_T`

Convert text_t to sip_content_length_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_content_length_t : The SIP.REQ.CONTENT_LENGTH or SIP.RES.CONTENT_LENGTH object can be treated as a SIP Header or as a Number. The numerical value for this object is derived from the value in the last instance of the Content-Length header.)

`Returns:` sip_content_length_t

`*TYPECAST_SIP_FROM_HEADER_T`

Convert text_t to sip_from_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_from_header_t : This object provides operations for parsing the SIP From header.)

`Returns:` sip_from_header_t

`*TYPECAST_SIP_HEADER_T` (text_t name)

Convert text_t to sip_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_header_t : When typecasting a Text object to SIP Header a header name must be provided.For example: SIP.REQ.HEADER("MyHdr").TYPECAST_SIP_HEADER_T("InHdr"))

`Parameters` (expressions not allowed) `:`

name- Header Name

`Returns:` sip_header_t

`*TYPECAST_SIP_HOSTNAME_T`

Convert text_t to sip_hostname_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_hostname_t : This object provides operations for parsing the SIP hostname as it appears at various places in the SIP protocol data. The format is abc.foo.com:5060.)

`Returns:` sip_hostname_t

`*TYPECAST_SIP_METHOD_T`

Convert text_t to sip_method_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_method_t : This object provides Text operations and SIP Request Method Enum operations on the SIP request method.)

`Returns:` sip_method_t

`*TYPECAST_SIP_TO_HEADER_T`

Convert text_t to sip_to_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_to_header_t : This object provides operations for parsing the SIP From header.)

`Returns:` sip_to_header_t

`*TYPECAST_SIP_URL_T`

Convert text_t to sip_url_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_url_t : SIP.REQ.URL provides operations for parsing and operating on the URL that is present in the first line of the SIP request header. The supported format is \[<protocol>://<hostname>\]<path>?<query>. The Text object backing a SIP URL object has the Text Mode set to URLENCODED by default.)

`Returns:` sip_url_t

`*TYPECAST_SIP_VERSION_T`

Convert text_t to sip_version_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_version_t : SIP.REQ.VERSION or SIP.RES.VERSION provide operations to extract SIP version information.)

`Returns:` sip_version_t

`*TYPECAST_SIP_VIA_HEADER_T`

Convert text_t to sip_via_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_via_header_t : This object provides operations for parsing the SIP Via header.)

`Returns:` sip_via_header_t

`*TYPECAST_SSLVPN_MODE_T`

Convert text_t to sslvpn_mode_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sslvpn_mode_t : This object provides Text operations and SSLVPN Mode Enum operations on the SSLVPN request method.)

`Returns:` sslvpn_mode_t

`*TYPECAST_SSL_TEXT_T` (text_t name)

Convert text_t to ssl_text_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ssl_text_t : Treat the underlying text object as SSL Text.)

`Parameters` (expressions not allowed) `:`

name- Name

`Returns:` ssl_text_t

`*TYPECAST_TCP_OPTIONS_T`

Convert text_t to tcp_options_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (tcp_options_t : TCP Protocol Options)

`Returns:` tcp_options_t

`*TYPECAST_TCP_OPTIONS_TYPE_T`

Convert text_t to tcp_options_type_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (tcp_options_type_t : TCP Protocol Options Type)

`Returns:` tcp_options_type_t

`*TYPECAST_TCP_REPEATER_OPTION_T`

Convert text_t to tcp_repeater_option_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (tcp_repeater_option_t : TCP Protocol Option : Repeater)

`Returns:` tcp_repeater_option_t

`*TYPECAST_TIME_AT`

Convert text_t to time_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (time_at : Treats a number value as number of seconds since GMT Jan 1 1970 0h 0m 0s.)

`Returns:` time_at

`*TYPECAST_TIME_LOCAL_AT`

Convert text_t to time_local_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (time_local_at : Treats a number value as number of seconds since GMT Jan 1 1970 0h 0m 0s as adjsuted for the local time zone.)

`Returns:` time_local_at

`*TYPECAST_TIME_T`

Convert text_t to time_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (time_t : This object treats a Text object as a date string. The formats supported are

1\. RFC822 :: Sun, 06 Nov 1994 08:49:37 GMT 2\. RFC850 :: Sunday, 06-Nov-94 08:49:37 GMT 3\. ASCTIME :: Sun Nov 6 08:49:37 1994 4\. ASCTIME like :: Sun Nov 6 08:49:37 1994 5\. ASCTIME like :: Sun Nov 06 08:49:37 1994 6\. Http Set-Cookie Expiry date :: Sun, 06-Nov-1994 08:49:37 GMT)

`Returns:` time_t

`*TYPECAST_UNSIGNED_LONG_AT`

Convert text_t to unsigned_long_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_at : Unsigned Long(64bit) Value)

`Returns:` unsigned_long_at

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error.)

`Parameters` (expressions not allowed) `:`

format- Format

`Returns:` unsigned_long_t

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format, ip_address_at default_value)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` unsigned_long_t

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format, unsigned_long_at default_value)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` unsigned_long_t

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format, num_at default_value)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` unsigned_long_t

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format, time_local_at default_value)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` unsigned_long_t

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format, time_at default_value)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX,

DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` unsigned_long_t

`*TYPECAST_UNUM_TEXT_T`

Convert text_t to unum_text_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unum_text_t : Provides operations to treat the underlying OctectString as Binary String or unsigned long value .)

`Returns:` unum_text_t

`*TYPECAST_URL_CATEGORY_T`

Convert text_t to url_category_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (url_category_t : Retrieves URL category and attributes from an URL)

`Returns:` url_category_t

`*TYPECAST_VENDOR_SPEC_APPID_AVP_T`

Convert text_t to vendor_spec_appid_avp_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (vendor_spec_appid_avp_t : Retrieves AVPs that are nested in the grouped AVP Vendor-Specific-Application-Id (code 260). The nested AVPs are:

- Vendor-Id
- Auth-Application-Id
- Acct-Application-Id

For example, to retrieve the Auth-Application-Id AVP from the Vendor-Specific-Application-Id AVP:

- For requests: DIAMETER.REQ.VENDOR_SPECIFIC_APPLICATION_ID.AUTH_APPLICATION_ID
- For responses: DIAMETER.RES.VENDOR_SPECIFIC_APPLICATION_ID.AUTH_APPLICATION_ID

)

`Returns:` vendor_spec_appid_avp_t

`*TYPECAST_VENDOR_SPEC_RADIUS_AVP_T`

Convert text_t to vendor_spec_radius_avp_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (vendor_spec_radius_avp_t :

- Vendor-Id

To retrieve the Vendor-Id from the Vendor-Specific AVP:

- RADIUS.REQ.VENDOR_SPECIFIC.VENDORID

)

`Returns:` vendor_spec_radius_avp_t

`*UNQUOTE` (`char` c)

If selected text is quoted by character c, Remove character c from beginning and end.

For example: Say the selected text is / "foo xyz bar " /. Then on executing UNQUOTE("") the selected text will become /foo xyz bar / This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

c- Character

`Returns:` text_t

`*URLSET_MATCHES_ANY` (text_t urlset_name)

Results in Boolean TRUE value if and only if the Text matches any of the patterns that are specified in the urlset named by the string argument. The matching is case-insensitive for domains, but case-sensitive for paths. For example:

- HTTP.REQ.HOST.APPEND(HTTP.REQ.URL).URLSET_MATCHES_ANY("urlset_forbidden") returns true when the combined domain and URL matches any pattern in the urlset whose name is "urlset_forbidden".

`Parameters` (expressions not allowed) `:`

urlset_name- urlset name

`Returns:` bool_at

`*URL_CATEGORIZE` (`uint` min_reputation, `uint` max_reputation)

Returns the URL category for the supplied URL with the given minimum and maximum reputation score. Where a score of 5 is most risky and 1 is least risky. If either score is set to 0, that bound would be ignored. By specifying the reputation scores, the function will returned the category with the highest score (most risky) based on the bounds. If there was an error getting the category or if the URL is invalid then it will result in an Undef error. For example: HTTP.REQ.HOST.APPEND(HTTP.REQ.URL).URL_CATEGORIZE(0, 0) returns value when the combined domain and URL is looked up for the URL category with the highest reputation score (most risky).

`Parameters` (expressions not allowed) `:`

min_reputation- Minimum reputation score of URL category

max_reputation- Maximum reputation score of URL category

`Returns:` url_category_t

`*URL_RESERVED_CHARS_SAFE`

Converts URL reserved characters to corresponding '%XX' values and retains the rest. This is a read only operation.

```
Based on RFC3986, following are considered URL unreserved characters:

    Alpha-numeric characters: a-z, A-Z, 0-9

    Hyphen and underscore: "-", "_"

    Dot: "."
```

```
Tilde: "~"
```

The rest are converted to %XX encoding, 'XX' is the hex-based representation of the input character. If the requirement is to encode all but URL safe characters, please consider using HTTP_URL_SAFE method.

`Returns:` text_t

`*XML_DECRYPT` (text_t certKeyName)

Decrypt the selected content, which was encrypted using the W3C XML Encryption standard.

`Parameters` (expressions not allowed) `:`

certKeyName- identifies the certkey object containing the RSA private key to be used to decrypt the bulk encryption key in the selected EncryptedData element.

`Returns:` text_t

`*XML_ENCRYPT` (text_t certKeyName, encrypt_method_e method)

Encrypt the selected cleartext using the W3C XML Encryption standard.

`Parameters` (expressions not allowed) `:`

certKeyName- identifies the certkey object containing an X.509 certificate with the RSA public key to be used to encrypt the generated bulk encryption key. Note that the certKey object need not, and usually will not, include the associated RSA private key.

method- specifies the bulk encryption method (rc4, des3, aes128, aes192, or aes256) used to encrypt the content.

`Returns:` text_t

`*XML_ENCRYPT` (text_t certKeyName, encrypt_method_e method, `uint` flags)

Encrypt the selected cleartext using the W3C XML Encryption standard.

`Parameters` (expressions not allowed) `:`

certKeyName- identifies the certkey object containing an X.509 certificate with the RSA public key to be used to encrypt the generated bulk encryption key. Note that the certKey object need not, and usually will not, include the associated RSA private key.

method- specifies the bulk encryption method (rc4, des3, aes128, aes192, or aes256) used to encrypt the content.

flags- optional bit mask to specify optional elements in the EncryptedData element. These are hints to tell the receiver what private key to use to decrypt the bulk encryption key, providing information from the certKey's X.509 certificate.

- 1 - include a KeyName element with the certKeyName;
- 2 - include a KeyValue element with the RSA public key from the certificate;
- 4 - include an X509IssuerSerial element with the certificate serial number and issuer DN;
- 8 - include an X509SubjectName element with the certificate subject DN;
- 16 - include an X509Certificate element with the entire certificate;

`Returns:` text_t

`*XPATH_HTML_WITH_MARKUP` (`xpath_str` xpathex)

Applies an XPath expression to the DOM for an HTML document and returns the selected node-set or string, including markup like element tags. node-sets are converted to strings using the standard XPath string conversion routine. The selected portion of the document can be used as the target for rewrite actions.

Examples: HTTP.REQ.BODY(1000).XPATH_HTML_WITH_MARKUP(xp%//md/head/title%) returns the <title> element in the document's <head> This can be used in a rewrite action to replace or delete the <title> element.

`Parameters` (expressions not allowed) `:`

xpathex- XPath Expression

`Returns:` text_t

`*XPATH_HTML` (`xpath_bool` xpathex)

Applies an XPath expression to the DOM for an HTML document and a boolean value.

Examples: HTTP.RES.BODY(1000).XPATH_HTML(xp%boolean(/md/head/meta)%) returns true if the <meta> element exists as a child of <head> element.

`Parameters` (expressions not allowed) `:`

xpathex- XPath Expression

`Returns:` bool_at

`*XPATH_HTML` (`xpath_double` xpathex)

Applies an XPath expression to the DOM for an HTML document and a double value.

Examples: HTTP.RES.BODY(1000).XPATH_HTML(xp%number(//video/@height)%) returns the numeric value of the height attribute of the first <video> element.

`Parameters` (expressions not allowed) `:`

xpathex- XPath Expression

`Returns:` double_at

`*XPATH_HTML` (`xpath_str` xpathex)

Applies an XPath expression to the DOM for an HTML document and returns the selected node-set or string. node-sets are converted to strings using the standard XPath string conversion routine.

Examples: HTTP.REQ.BODY(1000).XPATH_HTML(xp%//img/@src%) returns the string value of the src attribute of the first

AVP_UNUM_T

In Diameter AVP based expressions can be written as DIAMETER.REQ.AVP(<avpcode>). For example Auth-Application-Id AVP (AVP code 258) can be extracted as DIAMETER.REQ.AVP(258) For few of the important AVPs we provide aliases. For example this AVP based expression can also be written as DIAMETER.REQ.AUTH_APPLICATION_ID. This expression returns either a object of class avp_t or returns a numerical value (object of class unsigned_long_at). The numerical value for this object is derived from the value in first instance of the AVP.

This topic lists the expressions that are provided by this class.

`*Note` *: Expressions with the * symbol are inherited / promoted from avp_t unsigned_long_at

- `TYPECAST_AVP_T`

  Convert avp_unum_t to avp_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (avp_t : Operations that can be performed on the returned AVPs.

`Note:` An AVP can have multiple instances in a Diameter message. However, the system can access only the first 16 instances.

`Example:`

- To get the first value of AVP code 266 from a request, use: DIAMETER.REQ.AVP(266).VALUE(0).
- To get the fourth value of AVP code 266 from a request, use: DIAMETER.REQ.AVP(266).VALUE(3).
- To check if AVP code 1000 in the response has the vendor-specific bit set, use: DIAMETER.RES.AVP(1000).IS_VENDOR_SPECIFIC.

)

`Returns:` avp_t

`*TYPECAST_UNSIGNED_LONG_AT`

Convert avp_unum_t to unsigned_long_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_at : Unsigned Long(64bit) Value)

`Returns:` unsigned_long_at

`*ABS`

Return absolute double value of the double value.

`Returns:` double_at

`*ADD` (double_at i)

Return the Double Value after adding the argument to the current double value.

`Parameters``:`

i- Double

`Returns:` double_at

`*ADD` (ip_address_at i)

Return the Unsigned Long after adding the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*ADD` (num_at i)

Return the Unsigned Long after adding the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*ADD` (time_local_at i)

Return the Unsigned Long after adding the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*ADD` (time_at i)

Return the Unsigned Long after adding the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*ADD` (unsigned_long_at i)

Return the Unsigned Long after adding the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*AFTER_REGEX` (`re` regex)

Selects the text after the portion that matches the given regular expression argument. The first match is returned when multiple matches occur in the text. The match may occur anywhere within the text - if you wish to "anchor" this, use "\^" at the start of the regex and/or "$" at the end of the regex. When the regular expression does not match the given string, a Text object of length of 0 is returned.

Example: HTTP.REQ.HEADER("etag").AFTER_REGEX(re/KX/) will select "DAPPER" from "KXDAPPER". This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

regex- Regular Expression

`Returns:` text_t

`*AFTER_STR_ANY` (text_t patset_name)

Selects the Text that is present after the first occurrence of any of the strings that are bound to the patset named by the string argument. If there is no match to any of the strings bound to the patset in the current Text object then the result Text object has 0 length. The patset cannot have strings longer than 255 characters. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` text_t

`*AFTER_STR` (text_t s)

Selects the Text that is present after the first occurrence of the string argument. If there is no match for the argument in the current Text then the result Text object has 0 length. The input string cannot be bigger than 255 characters. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*APPEND` (bool_at b)

Appends the given boolean's string representation to the current string.

`Parameters``:`

b- the boolean value to append.

`Returns:` text_t

`*APPEND` (double_at i)

Appends the given double's string representation to the current string.

`Parameters``:`

i- the double value to append.

`Returns:` text_t

`*APPEND` (ip_address_at addr)

Appends the given IPv4's string representation to the current string.

`Parameters``:`

addr- the IPv4 address to append.

`Returns:` text_t

`*APPEND` (num_at i)

Appends the given number's string representation to the current string.

`Parameters``:`

i- the number value to append.

`Returns:` text_t

`*APPEND` (time_local_at t)

Appends the given time's string representation to the current string.

`Parameters``:`

t- the time value to append.

`Returns:` text_t

`*APPEND` (time_at t)

Appends the given time's string representation to the current string.

`Parameters``:`

t- the time value to append.

`Returns:` text_t

`*APPEND` (unsigned_long_at i)

Appends the given unsigned long's string representation to the current string.

`Parameters``:`

i- the unsigned long value to append.

`Returns:` text_t

`*APPEND` (ipv6_address_at addr)

Appends the given IPv6's string representation to the current string.

`Parameters``:`

addr- the IPv6 address to append.

`Returns:` text_t

`*APPEND` (ipv6_subnet_at addr)

Appends the given IPv6 subnet's string representation to the current string.

`Parameters``:`

addr- the IPv6 subnet to append.

`Returns:` text_t

`*APPEND` (mac_address_at addr)

Appends the given MAC's string representation to the current string.

`Parameters``:`

addr- the MAC address to append.

`Returns:` text_t

`*APPEND` (text_t str)

Appends the given string to the string representation of the current unsigned long.

`Parameters``:`

str- the string to append.

`Returns:` text_t

`*APPEND` (time_at t)

Appends the given time's string representation to the current string.

`Parameters``:`

t- the time value to append.

`Returns:` text_t

`*AS_MICROSEC_STR`

Returns the current system time in the following format Format: Wday, day Month year hh:mm:ss.ffffff GMT ffffff represents microseconds Examples:

Mon, 05 Mar 2018 10:23:36.568419 GMT

`Returns:` text_t

`*AS_MILLISEC_STR`

Returns the current system time in the following format Format: Wday, day Month year hh:mm:ss.fff GMT fff represents milliseconds Examples:

Mon, 05 Mar 2018 10:23:36.568 GMT

`Returns:` text_t

`*AS_NANOSEC_STR`

Returns the current system time in the following format Format: Wday, day Month year hh:mm:ss.fffffffff GMT fffffffff represents nanoseconds Accuracy may be at larger granularity than nanosecond resolution. Examples:

Mon, 05 Mar 2018 10:23:36.568419567 GMT

`Returns:` text_t

`*AVPLIST_AFTER`

Returns the region after this AVP in diameter message (or in other words returns location at end of this AVP and length covering end of this AVP to end of diameter message. If this AVP is inside a Grouped AVP, this method returns region after this AVP in parent Grouped AVP.

`Returns:` text_t

`*AVPLIST_BEFORE`

Returns the region till this AVP in diameter message (or in other words returns location at start of AVPs and length equal to offset of this AVP). If this AVP is inside a Grouped AVP, this method returns region till this AVP in parent AVP.

`Returns:` text_t

`*AVP` (`uint` avpcode)

Returns the AVP nested inside the GROUPED AVP (the Data field is a sequence of AVPs).

For example, to retrieve AVP(263) that is nested in AVP(99999) in a request, the expression is: DIAMETER.REQ.AVP(999999).AVP(263).

`Parameters` (expressions not allowed) `:`

avpcode- AVP code

`Returns:` avp_t

`*AVP` (`uint` avpcode, `uint` vendorid)

Returns the specified AVP in given vendor-id namespace and that is nested inside a GROUPED AVP in the message.

For example, to get the AVP with code 1005 and VendorId 10415 from a Request, that is nested inside 1001 (vendor-id 10415). Use this expression: DIAMETER.REQ.AVP(1001, 10415).AVP(1004, 10415).

`Note:` To get AVP that is nested inside a grouped AVP, use the AVP method from the avp_t class.

`Parameters` (expressions not allowed) `:`

avpcode- AVP code

vendorid- Vendor Id

`Returns:` avp_t

`*B64DECODE`

Decodes the selected text using base64 decoding.

For example, the string "TWFu" is converted to "Man"

`Returns:` text_t

`*B64ENCODE`

Encodes the selected text using base64 encoding.

For example, the string "Man" is converted to "TWFu"

`Returns:` text_t

`*BEFORE_REGEX` (`re` regex)

Selects the text before the portion that matches the given regular expression argument. The first match is returned when multiple matches occur in the text. The match may occur anywhere within the text - if you wish to "anchor" this, use "\^" at the start of the regex and/or "$" at the end of the regex. When the regular expression does not match the given string, a Text object of length of 0 is returned.

For example: HTTP.RES.HEADER("content-type").BEFORE_REGEX(re#/#) will select "text" from "text/plain". This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed)`:`

regex- Regular Expression

`Returns:` text_t

`*BEFORE_STR_ANY` (text_t patset_name)

Selects the Text that is present before the first occurrence of any of the strings that are bound to the patset or datasetnamed by the string argument. If there is no match to any of the strings bound to the patset in the current Text object then the result Text object has 0 length. The patset cannot have strings longer than 255 characters. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed)`:`

patset_name- Pattern Set Name

`Returns:` text_t

`*BEFORE_STR` (text_t s)

Selects the Text that is present before the first occurrence of the string argument. If there is no match for the argument in the current Text object then the result Text object has 0 length. The input string cannot be bigger than 255 characters. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*BETWEEN` (text_t start, text_t end)

Results in Boolean TRUE value if length of the Text object is greater than or equal to the sum of the Start and End argument lengths and if the prefix of the Text object matches the Start string argument and if the Suffix of the Text object matches the End string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

start- Start

end- End

`Returns:` bool_at

`*BETWEEN` (double_at i, double_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (double_at i, ip_address_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (double_at i, num_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (double_at i, time_local_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (double_at i, time_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (double_at i, unsigned_long_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (ip_address_at i, double_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (ip_address_at i, ip_address_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (ip_address_at i, num_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (ip_address_at i, time_local_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (ip_address_at i, time_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (ip_address_at i, unsigned_long_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (num_at i, double_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (num_at i, ip_address_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (num_at i, num_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (num_at i, time_local_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (num_at i, time_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (num_at i, unsigned_long_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (time_local_at i, double_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (time_local_at i, ip_address_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (time_local_at i, num_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (time_local_at i, time_local_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (time_local_at i, time_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (time_local_at i, unsigned_long_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (time_at i, double_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (time_at i, ip_address_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (time_at i, num_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (time_at i, time_local_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (time_at i, time_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (time_at i, unsigned_long_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (unsigned_long_at i, double_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (unsigned_long_at i, ip_address_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (unsigned_long_at i, num_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (unsigned_long_at i, time_local_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (unsigned_long_at i, time_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (unsigned_long_at i, unsigned_long_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BIN_DECODE` (binary_encoding_e encoding)

Decode the encoded input into its original byte sequence. An incorrectly enooded input will result in an Undef error.

`Parameters` (expressions not allowed)`:`

encoding- specifies how the bytes are encoded.

`Returns:` text_t

`*BIN_ENCODE` (binary_encoding_e encoding)

Encode the input byte sequence. Note that BIN_ENCODE(hex_colons) is equivalent to BLOB_TO_HEX().

`Parameters` (expressions not allowed) `:`

encoding- specifies how the bytes are to be encoded.

`Returns:` text_t

`*BITAND` (ip_address_at i)

Return the Unsigned Long Value after bitwise ANDing the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*BITAND` (num_at i)

Return the Unsigned Long Value after bitwise ANDing the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*BITAND` (time_local_at i)

Return the Unsigned Long Value after bitwise ANDing the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*BITAND` (time_at i)

Return the Unsigned Long Value after bitwise ANDing the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*BITAND` (unsigned_long_at i)

Return the Unsigned Long Value after bitwise ANDing the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*BITNEG`

Return the Unsigned Long Value after bitwise negating the current unsigned long value.

`Returns:` unsigned_long_at

`*BITOR` (ip_address_at i)

Return the Unsigned Long Value after bitwise ORing the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*BITOR` (num_at i)

Return the Unsigned Long Value after bitwise ORing the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*BITOR` (time_local_at i)

Return the Unsigned Long Value after bitwise ORing the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*BITOR` (time_at i)

Return the Unsigned Long Value after bitwise ORing the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*BITOR` (unsigned_long_at i)

Return the Unsigned Long Value after bitwise ORing the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*BITXOR` (ip_address_at i)

Return the Unsigned Long Value after bitwise XORing the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*BITXOR` (num_at i)

Return the Unsigned Long Value after bitwise XORing the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*BITXOR` (time_local_at i)

Return the Unsigned Long Value after bitwise XORing the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*BITXOR` (time_at i)

Return the Unsigned Long Value after bitwise XORing the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*BITXOR` (unsigned_long_at i)

Return the Unsigned Long Value after bitwise XORing the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*BLOB_TO_HEX`

Convert to hexadecimal representation and select text.

For example, the byte string abc is converted to 61:62:63.

`Returns:` text_t

`*COMPARE` (text_t s)

Results in a Number Value which is the result of comparison of the input argument with the Text object. The result is greater than 0 if the Text object is lexicographically greater than the argument. The result is 0 if the Text object and the argument match. The result is less than 0 if the Text object is lexicographically lesser than the argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` num_at

`*CONTAINS_ANY` (text_t patset_name)

Results in Boolean TRUE value if the Text contains any of the strings that are bound to the patset or dataset named by the string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` bool_at

`*CONTAINS_INDEX` (text_t patset_name)

Returns the numerical index of the matching string, if the Text contains any of the strings that are bound to the patset or dataset named by the string argument. Returns 0 if there is no match. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` num_at

`*CONTAINS` (text_t s)

Results in Boolean TRUE value if the Text contains the string given in the argument. The input string cannot be bigger than 255 characters. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*COUNT`

Returns the number of occurences of an AVP in diameter message. The system does not keep track of more than 16 AVP occurences of an AVP. The result will be undefined if there are more than 16 instances of that AVP.

`Returns:` num_at

`*CRC32`

Returns a 32-bit integer computed by applying a CRC (cyclic redundancy check) function to the selected text. This is the CRC function used by Ethernet, MPEG-2, PKZIP, GZIP, PNG, and many other applications. For example, the expression to compute the CRC value of the (first 1000 bytes of the) body of an HTTP request is: HTTP.REQ.BODY(1000).CRC32

`Returns:` num_at

`*DECODE_USING_TEXT_MODE`

Decodes the selected text using the currently configured text encoding methods like URLENCODED, BACKSLASH_ENCODED, PLUS_AS_SPACE, NOURLENCODED, NO_BACKSLASH_ENCODED and NO_PLUS_AS_SPACE. Text encoding methods are set using SET_TEXT_MODE method.

`Returns:` text_t

`*DECRYPT`

Decrypt the selected base64-encoded ciphertext using the configured encryptionParams.

`Returns:` text_t

`*DECRYPT` (binary_encoding_e in_encoding)

Decrypt the selected ciphertext using the configured encryptionParams.

`Parameters` (expressions not allowed)`:`

in_encoding- specifies how the input ciphertext is encoded. If the ciphertext is not encoded as specified, causes an Undef error.

`Returns:` text_t

`*DECRYPT` (text_t encryptionKey)

Decrypt the selected base64-encoded encrypted bytes using the configured encryption key.

`Parameters` (expressions not allowed) `:`

encryptionKey- identifies the encryptionKey object to provide the cipher method, mode, padding, key, encrypted format and optional initialization vector (IV).

`Returns:` text_t

`*DECRYPT` (text_t encryptionKey, binary_encoding_e in_encoding)

Decrypt the selected base64-encoded encrypted bytes using the configured encryption key.

`Parameters` (expressions not allowed) `:`

encryptionKey- identifies the encryptionKey object to provide the cipher method, mode, padding, key, encrypted format, and optional initialization vector (IV).

in_encoding- specifies how the input ciphertext is encoded. If the ciphertext is not encoded as specified, causes an Undef error.

`Returns:` text_t

`*DIGEST` (digest_method_e method)

Returns a byte sequence computed by applying the the specified message digest method to the selected text.

`Parameters` (expressions not allowed) `:`

method- digest method to apply to the input text

`Returns:` text_t

`*DIV` (double_at i)

Return the Double Value after dividing the current double value by the argument.

`Parameters``:`

i- Double

`Returns:` double_at

`*DIV` (ip_address_at i)

Return the Unsigned Long Value after dividing the current unsigned long value by the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*DIV` (num_at i)

Return the Unsigned Long Value after dividing the current unsigned long value by the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*DIV` (time_local_at i)

Return the Unsigned Long Value after dividing the current unsigned long value by the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*DIV` (time_at i)

Return the Unsigned Long Value after dividing the current unsigned long value by the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*DIV` (unsigned_long_at i)

Return the Unsigned Long Value after dividing the current unsigned long value by the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*ENCRYPT`

Encrypt the selected plaintext bytes using the configured encryptionParams. The resulting ciphertext is base64-encoded.

`Returns:` text_t

`*ENCRYPT` (binary_encoding_e out_encoding)

Encrypt the selected plaintext bytes using the configured encryptionParams.

`Parameters` (expressions not allowed)`:`

out_encoding- specifies how the resulting ciphertext is encoded.

`Returns:` text_t

`*ENCRYPT` (text_t encryptionKey)

Encrypt the selected cleartext bytes using the configured encryption key.

`Parameters` (expressions not allowed)`:`

encryptionKey- identifies the encryptionKey object to provide the cipher method, mode, padding, key, encrypted format and optional initialization vector (IV).

`Returns:` text_t

`*ENCRYPT` (text_t encryptionKey, binary_encoding_e out_encoding)

Encrypt the selected cleartext bytes using the configured encryption key.

`Parameters` (expressions not allowed)`:`

encryptionKey- identifies the encryptionKey object to provide the cipher method, mode, padding, key, encrypted format and optional initialization vector (IV).

out_encoding- specifies how the resulting ciphertext is encoded.

`Returns:` text_t

`*ENDSWITH_ANY` (text_t patset_name)

Results in Boolean TRUE value if the Text ends with any of the strings that are bound to the patset or dataset named by the string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` bool_at

`*ENDSWITH_INDEX` (text_t patset_name)

Returns the numerical index of the matching string, if the Text ends with any of the strings that are bound to the patset or dataset named by the string argument. Returns 0 if there is no match. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` num_at

`*ENDSWITH` (text_t end)

Results in Boolean TRUE value if a suffix of the Text object matches the string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

end- String

`Returns:` bool_at

`*EQUALS_ANY` (text_t patset_name)

Results in Boolean TRUE value if the Text equals any of the strings that are bound to the patset or dataset named by the string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` bool_at

`*EQUALS_INDEX` (text_t patset_name)

Returns the numerical index of the matching string, if the Text equals any of the strings that are bound to the patset or dataset named by the string argument. Returns 0 if there is no match. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` num_at

`*EQ` (text_t s)

Results in Boolean TRUE value if the Text object matches the input argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*EQ` (double_at i)

Returns Boolean TRUE if the double value is equal to the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`*EQ` (ip_address_at i)

Returns Boolean TRUE if the unsigned long is equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*EQ` (num_at i)

Returns Boolean TRUE if the unsigned long is equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*EQ` (time_local_at i)

Returns Boolean TRUE if the unsigned long is equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*EQ` (time_at i)

Returns Boolean TRUE if the unsigned long is equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*EQ` (unsigned_long_at i)

Returns Boolean TRUE if the unsigned long is equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*EXISTS`

Returns true if the AVP exists in the message.

`Returns:` bool_at

`*GET_SIGNED16` (`uint` n, endian_e endianness)

Get the 16-bit signed binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

endianness- Select little or big endian

`Returns:` num_at

`*GET_SIGNED32` (`uint` n, endian_e endianness)

Get the 32-bit signed binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

endianness- Select little or big endian

`Returns:` num_at

`*GET_SIGNED8` (`uint` n)

Get the 8-bit signed binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

`Returns:` num_at

`*GET_UNSIGNED16` (`uint` n, endian_e endianness)

Get the 16-bit unsigned binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

endianness- Select little or big endian

`Returns:` num_at

`*GET_UNSIGNED32` (`uint` n, endian_e endianness)

Get the 32-bit unsigned binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

endianness- Select little or big endian

`Returns:` unsigned_long_at

`*GET_UNSIGNED64` (`uint` n, endian_e endianness)

Get the 64-bit unsigned binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

endianness- Select little or big endian

`Returns:` unsigned_long_at

`*GET_UNSIGNED8` (`uint` n)

Get the 8-bit unsigned binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

`Returns:` num_at

`*GET_URLSET_METADATA` (text_t urlset_name)

Returns metadata value corresponding to pattern in the urlset. The matching is case-insensitive for domains, but case-sensitive for paths. If no pattern is matched within the urlset, the return value is a NULL string. For example:

- HTTP.REQ.HOST.APPEND(HTTP.REQ.URL).GET_URLSET_METADATA("urlset_forbidden") returns value when the combined domain and URL is looked up in the urlset whose name is "urlset_forbidden".

`Parameters` (expressions not allowed) `:`

urlset_name- urlset name

`Returns:` text_t

`*GE` (text_t s)

Results in Boolean TRUE value if the Text object is greater than or equal to the input argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*GE` (double_at i)

Returns Boolean TRUE if the double value is greater than or equal to the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`*GE` (ip_address_at i)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*GE` (num_at i)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*GE` (time_local_at i)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*GE` (time_at i)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*GE` (unsigned_long_at i)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*GRPC`

Interprets a text_t string as a Protocol Buffer (protocol_buffer_t type). Example: HTTP.REQ.BODY(1000).GRPC.STRING(1).EQ("bookname")

`Returns:` protocol_buffer_t

`*GT` (text_t s)

Results in Boolean TRUE value if the Text object is greater than the input argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*GT` (double_at i)

Returns Boolean TRUE if the double value is greater than the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`*GT` (ip_address_at i)

Returns Boolean TRUE if the unsigned long value is greater than the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*GT` (num_at i)

Returns Boolean TRUE if the unsigned long value is greater than the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*GT` (time_local_at i)

Returns Boolean TRUE if the unsigned long value is greater than the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*GT` (time_at i)

Returns Boolean TRUE if the unsigned long value is greater than the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*GT` (unsigned_long_at i)

Returns Boolean TRUE if the unsigned long value is greater than the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*HASH`

Returns a positive 31 bit integer value computed by applying a proprietary NetScaler hash function to the selected text. This function is not case- sensitive and ignores whitespaces. For example, applying the HASH function to two strings "Ab c" and "abc" would produce the same value. This function should not be used for security purposes; use instead the DIGEST function with one of the standard digest methods.

`Returns:` num_at

`*HMAC` (text_t hmacKey)

Returns a byte sequence computed by applying the HMAC (Hash Message Authenticastion Code) function to the selected text using the configured HMAC key.

`Parameters` (expressions not allowed) `:`

hmacKey- indentifies the hmacKey object to provide the digest (hash) method and the key.

`Returns:` text_t

`*HMAC` (text_t hmacKey, binary_encoding_e out_encoding)

Returns a byte sequence computed by applying the HMAC (Hash Message Authenticastion Code) function to the selected text using the configured HMAC key .

`Parameters` (expressions not allowed) `:`

hmacKey- indentifies the hmacKey object to provide the digest (hash) method and the key.

out_encoding- specifies how the resulting HMAC is encoded.

`Returns:` text_t

`*HTML_XML_SAFE`

Apply XML safe transform and select text.

Converts '<', '>' and '&' in the input text to '<', '>' and '&' respectively; other characters in the input are not modified. This transform safeguards against XSS based attacks. This is a read only operation.

`Returns:` text_t

`*HTTP_HEADER_SAFE`

Apply Header safe transform and select text. Converts all new line ('\\n') characters present in the input text to '%0A' so that they can safely be used in HTTP headers. This transform safeguards against response-splitting attacks. This is a read only operation.

`Returns:` text_t

`*HTTP_URL_SAFE`

Apply URL safe transform and select text. Converts URL unsafe characters to corresponding '%xx' values and retains the rest. This is a read only operation.

```
Based on RFC2396, following are considered URL safe characters:

    Alpha-numeric characters: a-z, A-Z, 0-9

    Hyphen and underscore: "-", "_"

    Dot: "."

    Exclamation mark: "!"

    Tilde: "~"

    Asterix: "&ast;"

    Single quote: "'"

    Open and close parentheses: "(", ")"

    Semi-colon: ";"

    Colon: ":"

    At symbol: "@"
```

```
Question mark: "?"

Equals: "="

Dollar: "$"

Percent: "%"

Ampersand: "&"

Plus: "+"

Comma: ","

Forward slash: ".html"
```

The rest are converted to %XX encoding, 'XX' is the hex-based representation of the input character. If the requirement is to encode all but URL unreserved characters, please consider using URL_RESERVED_CHARS_SAFE method.

`Returns:` text_t

`*INSTANCE` (`uint` instanceno)

Returns instances of the AVP.

The first instance of the AVP can be retrieved by simply using the expression: DIAMETER.REQ.AVP(266). However, subsequent instances must be retrieved using this method.

INSTANCE(0) retrieves the first instance, INSTANCE(1) retrieves the second instance, and so on.

For example, lets assume the Route-Record AVP (code 282) has three instances in a request.

- Route-Record: abcd1.netscaler.com
- Route-Record: abcd2.netscaler.com
- Route-Record: abcd3.netscaler.com

To get the second instance, the expression would be: DIAMETER.REQ.AVP(282).INSTANCE(1).

`Parameters` (expressions not allowed) `:`

instanceno- AVP instance number. Maximum value: 15.

`Returns:` avp_t

`*IS_BOOL_AT`

Results in Boolean TRUE value if the Text is of boolean type.

`Returns:` bool_at

`*IS_DOUBLE_AT`

Results in Boolean TRUE value if the Text is of double data type.

`Returns:` bool_at

`*IS_IPV6_AT`

Results in Boolean TRUE value if the Text is of IPv6 data type.

`Returns:` bool_at

`*IS_IPV6_SUBNET_AT`

Results in Boolean TRUE value if the Text is of IPv6 subnet data type.

`Returns:` bool_at

`*IS_IP_AT`

Results in Boolean TRUE value if the Text is of IPv4 data type.

`Returns:` bool_at

`*IS_MAC_ADDRESS_AT`

Results in Boolean TRUE value if the Text is of mac address data type.

`Returns:` bool_at

`*IS_MANDATORY`

Returns true if the AVP has the Mandatory bit set.

`Returns:` bool_at

`*IS_NUM_AT`

Results in Boolean TRUE value if the Text is of number type.

`Returns:` bool_at

`*IS_NUM_AT` (num_format_e format)

Results in Boolean TRUE value if the Text is of number type with given input base.

`Parameters` (expressions not allowed) `:`

format- number format

`Returns:` bool_at

`*IS_STRINGMAP_KEY` (text_t string_map_name)

Returns true if the string that it operates on is present in the string map. Text mode IGNORECASE, NOIGNORECASE - controls whether key lookup in string map is case sensitive or not. For example:

- HTTP.REQ.URL.IS_STRINGMAP_KEY("url_stringmap") returns true if value of HTTP.REQ.URL is present as key in the string map whose name is "url_stringmap".
- HTTP.REQ.URL.SET_TEXT_MODE(IGNORECASE). IS_STRINGMAP_KEY("url_stringmap") returns true if value of HTTP.REQ.URL is present as key in the string map whose name is "url_stringmap". Key lookup in this case is done case-insensitively.

`Parameters` (expressions not allowed) `:`

string_map_name- identifies the string map.

`Returns:` bool_at

`*IS_TIME_AT`

Results in Boolean TRUE if the Text follows any of the standard time formats given below, otherwise false. Tue, 05 Nov 1994 08:12:31 GMT RFC822 Tuesday, 05-Nov-94 08:12:31 GMT RFC850 Tue Nov 4 08:12:31 1994 asctime

`Returns:` bool_at

`*IS_UNSIGNED_LONG_AT`

Results in Boolean TRUE value if the Text is of unsigned long data type.

`Returns:` bool_at

`*IS_UNSIGNED_LONG_AT` (num_format_e format)

Results in Boolean TRUE value if the Text is of unsigned long data type with given input base.

`Parameters` (expressions not allowed) `:`

format- number format

`Returns:` bool_at

`*IS_VENDOR_SPECIFIC`

Returns true if the AVP has Vendor-Specific bit (V) set.

`Returns:` bool_at

`*JWT_VERIFY_CERTKEY` (text_t certkey_name)

Verifies the signature on the input JSON Web Token (JWT), using the RSA public key in the X.509 certificate in the specified certkey object. The token has the format HEADER.PAYLOAD.SIGNATURE where

- HEADER is a base64-encoded JSON structure indicating a signature algorithm and token type, e.g.'{"alg":"RS256","typ":"JWT"}'
- PAYLOAD is a base64-encoded JSON structure with asserted claims, e.g. '{"loggedInAs":"admin","iat":1422779638}'
- SIGNATURE is the base64-encoded bytes for the signature on HEADER.PAYLOAD.

Returns true if the signature is verified for the header and payload using the specified public key; false if the signature is not verified

`Parameters``:`

certkey_name- identifies the certkey object containing an X.509 certificate holding the RSA public key. Results in an Undef error if the certkey object does not exist or does not contain an X.509 certificate with an RSA public key, if the token is not correctly formatted, or if the verification operation cannot complete.

`Returns:` bool_at

`*JWT_VERIFY_XML` (text_t xml_pkey)

Verifies the signature on the input JSON Web Token (JWT), using the RSA public key supplied by the specified XML element. The token has the format HEADER.PAYLOAD.SIGNATURE where

- HEADER is a base64-encoded JSON structure indicating a signature algorithm and token type, e.g.'{"alg":"RS256","typ":"JWT"}'
- PAYLOAD is a base64-encoded JSON structure with asserted claims, e.g. '{"loggedInAs":"admin","iat":1422779638}'
- SIGNATURE is the base64-encoded bytes for the signature on HEADER.PAYLOAD.

Returns true if the signature is verified for the header and payload using the specified public key; false if the signature is not verified

`Parameters``:`

xml_pkey- an expression that supplies an <RSAKeyValue> element with the public key. Results in an Undef error if the XML element is invalid or does not correctly specify an RSA public key, if the token is not correctly formatted, or if the verification operation cannot complete.

`Returns:` bool_at

`*LENGTH`

Returns the AVP length including AVP header.

If the AVP is not present, it returns length 0. If multiple occurences of the AVP exist, it returns the length of first occurence.

`Returns:` num_at

`*LE` (text_t s)

Results in Boolean TRUE value if the Text object is less than or equal to the input argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*LE` (double_at i)

Returns Boolean TRUE if the double value is lesser than or equal to the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`*LE` (ip_address_at i)

Returns Boolean TRUE if the unsigned long value is lesser than or equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*LE` (num_at i)

Returns Boolean TRUE if the unsigned long value is lesser than or equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*LE` (time_local_at i)

Returns Boolean TRUE if the unsigned long value is lesser than or equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*LE` (time_at i)

Returns Boolean TRUE if the unsigned long value is lesser than or equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*LE` (unsigned_long_at i)

Returns Boolean TRUE if the unsigned long value is lesser than or equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*LOCATION_LONG`

Get the location qualifier from CLIENT.IP.SRC.LOCATION.GET(n) (ISO short name) and then convert it to human readable long name. This conversion is valid only for country names. Correct Country qualifier value (number) in GET(n) is left up to the user as qualifiers are user configurable. Expression example: CLIENT.IP.SRC.LOCATION.GET(1).LOCATION_LONG For example: Data from each expression CLIENT.IP.SRC.LOCATION: NA.US.California.SantaClara.*.* CLIENT.IP.SRC.LOCATION.GET(1): US CLIENT.IP.SRC.LOCATION.GET(1).LOCATION_LONG: United States

`Returns:` text_t

`*LSHIFT` (`uint` i)

Return the Unsigned Long Value after bitwise left shifting the current number value by the argument number of bits. Note that the number of bits shifted is i modulo 64.

`Parameters``:`

i- Left Shift Length

`Returns:` unsigned_long_at

`*LT` (text_t s)

Results in Boolean TRUE value if the Text object is less than the input argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*LT` (double_at i)

Returns Boolean TRUE if the double value is lesser than the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`*LT` (ip_address_at i)

Returns Boolean TRUE if the unsigned long value is lesser than the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*LT` (num_at i)

Returns Boolean TRUE if the unsigned long value is lesser than the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*LT` (time_local_at i)

Returns Boolean TRUE if the unsigned long value is lesser than the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*LT` (time_at i)

Returns Boolean TRUE if the unsigned long value is lesser than the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*LT` (unsigned_long_at i)

Returns Boolean TRUE if the unsigned long value is lesser than the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*MAP_STRING_DEFAULT_TO_KEY` (text_t string_map_name)

Returns the value corresponding to the key in the string map. This is similar to the MAP_STRING method, but if the key is not present then instead of returning a null string, it returns the key itself. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

string_map_name- identifies the string map.

`Returns:` text_t

`*MAP_STRING` (text_t string_map_name)

Returns value corresponding to key in the string map. Key is the string that it is given as input. Text mode IGNORECASE, NOIGNORECASE - controls whether key lookup in string map is case sensitive or not. For example:

- HTTP.REQ.URL.MAP_STRING("url_stringmap") returns value when the value of HTTP.REQ.URL is used as key in the string map whose name is "url_stringmap".
- HTTP.REQ.URL.SET_TEXT_MODE(IGNORECASE). MAP_STRING("url_stringmap") returns value when the value of HTTP.REQ.URL is used as key in the string map whose name is "url_stringmap". Key lookup in this case is done case-insensitively.

`Parameters` (expressions not allowed) `:`

string_map_name- identifies the string map.

`Returns:` text_t

`*MARK_SAFE`

Mark the PIXL expression safe without applying any safe transform.

`Returns:` text_t

`*MAX` (text_t s)

Compares the string argument with the current string and returns the max string. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*MAX` (double_at i)

Return the maximum double value after comparing the argument with the current double value.

`Parameters``:`

i- Double

`Returns:` double_at

`*MAX` (ip_address_at i)

Return the maximum unsigned long value after comparing the argument value to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MAX` (num_at i)

Return the maximum unsigned long value after comparing the argument value to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MAX` (time_local_at i)

Return the maximum unsigned long value after comparing the argument value to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MAX` (time_at i)

Return the maximum unsigned long value after comparing the argument value to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MAX` (unsigned_long_at i)

Return the maximum unsigned long value after comparing the argument value to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MIN` (text_t s)

Compares the string argument with the current string and returns the min string. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*MIN` (double_at i)

Return the minimum double value after comparing the argument with the current double value.

`Parameters``:`

i- Double

`Returns:` double_at

`*MIN` (ip_address_at i)

Return the minimum unsigned long value after comparing the argument value to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MIN` (num_at i)

Return the minimum unsigned long value after comparing the argument value to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MIN` (time_local_at i)

Return the minimum unsigned long value after comparing the argument value to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MIN` (time_at i)

Return the minimum unsigned long value after comparing the argument value to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MIN` (unsigned_long_at i)

Return the minimum unsigned long value after comparing the argument value to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MOD` (ip_address_at i)

Return the Unsigned Long Value that is the renaminder after dividing the current unsigned long value by the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MOD` (num_at i)

Return the Unsigned Long Value that is the renaminder after dividing the current unsigned long value by the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MOD` (time_local_at i)

Return the Unsigned Long Value that is the renaminder after dividing the current unsigned long value by the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MOD` (time_at i)

Return the Unsigned Long Value that is the renaminder after dividing the current unsigned long value by the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MOD` (unsigned_long_at i)

Return the Unsigned Long Value that is the renaminder after dividing the current unsigned long value by the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MUL` (double_at i)

Return the Double Value after multiplying the argument to the current double value.

`Parameters``:`

i- Double

`Returns:` double_at

`*MUL` (ip_address_at i)

Return the Unsigned Long Value after multiplying the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MUL` (num_at i)

Return the Unsigned Long Value after multiplying the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MUL` (time_local_at i)

Return the Unsigned Long Value after multiplying the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MUL` (time_at i)

Return the Unsigned Long Value after multiplying the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MUL` (unsigned_long_at i)

Return the Unsigned Long Value after multiplying the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*NEG`

Return the Double Value after negating the current double value.

`Returns:` double_at

`*NE` (text_t s)

Results in Boolean TRUE value if the Text object is not equal to the input argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*NE` (double_at i)

Returns Boolean TRUE if the double value is not equal to the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`*NE` (ip_address_at i)

Returns Boolean TRUE if the unsigned long value is not equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*NE` (num_at i)

Returns Boolean TRUE if the unsigned long value is not equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*NE` (time_local_at i)

Returns Boolean TRUE if the unsigned long value is not equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*NE` (time_at i)

Returns Boolean TRUE if the unsigned long value is not equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*NE` (unsigned_long_at i)

Returns Boolean TRUE if the unsigned long value is not equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*NORMALIZE_URL`

Normalize URL. Normalizes a URL by doing "percent" decoding. See the description for URLENCODED in the SET_TEXT_MODE function. This performs the equivalent of SET_TEXT_MODE(URLENCODED).DECODE_USING_TEXT_MODE, except that it does not change the value of the current text mode.

`Returns:` text_t

`*PKEY_ENCRYPT_PEM_NO_PADDING` (text_t pem_pkey)

Encrypts the input text using the RSA public key provided by the PEM string and RSA_NO_PADDING padding method. The input text to be encrypted cannot be longer than the public key length minus 11 bytes for padding. For example, for a 1024-bit (128 byte) key, the input text cannot be longer than 128 - 11 = 117 bytes. An Undef error will occur if the input text is too long. A null input will also cause an Undef error. Returns the (unencoded binary) encrypted text, which is typically base-64 encoded for use in a message.

`Parameters``:`

pem_pkey- a text expression that supplies a RSA public key in the PEM format. If the text value is not a valid PEM RSA PUBLIC KEY encoding, an Undef error will occur. Example (a 1024-bit public key):

```
"-----BEGIN RSA PUBLIC KEY-----" +

"MIGJAoGBAKl5vgQEj73Kxp+9yn1v5gPR1pnc4oLM2a0kaWwBOsB6rzCIy6znwnvw" +

"CY1xRvQhRlJSAyJbloL7wZFIJ2FOR8Cz+8ZQWXU2syG+udi4EnWqLgFYowF9zK+o" +

"79az597eNPAjsHZ/C2oL/+6qY5a/f1z8bQPrHC4GpFfAEJhh/+NnAgMBAAE=" +
```

```
"-----END RSA PUBLIC KEY-----"
```

`Returns:` text_t

`*PKEY_ENCRYPT_PEM` (text_t pem_pkey)

Encrypts the input text using the RSA public key provided by the PEM string and the RSA_PKCS1_PADDING padding method. The input text to be encrypted cannot be longer than the public key length minus 11 bytes for padding. For example, for a 1024-bit (128 byte) key, the input text cannot be longer than 128 - 11 = 117 bytes. An Undef error will occur if the input text is too long. A null input will also cause an Undef error. Returns the (unencoded binary) encrypted text, which is typically base-64 encoded for use in a message.

`Parameters``:`

pem_pkey- a text expression that supplies a RSA public key in the PEM format. If the text value is not a valid PEM RSA PUBLIC KEY encoding, an Undef error will occur. Example (a 1024-bit public key):

```
"-----BEGIN RSA PUBLIC KEY-----" +

"MIGJAoGBAKl5vgQEj73Kxp+9yn1v5gPR1pnc4oLM2a0kaWwBOsB6rzCIy6znwnvw" +

"CY1xRvQhRlJSAyJbloL7wZFIJ2FOR8Cz+8ZQWXU2syG+udi4EnWqLgFYowF9zK+o" +

"79az597eNPAjsHZ/C2oL/+6qY5a/f1z8bQPrHC4GpFfAEJhh/+NnAgMBAAE=" +

"-----END RSA PUBLIC KEY-----"
```

`Returns:` text_t

`*PKEY_SIGN_CERTKEY` (text_t certkey_name)

Generates a binary digital signature using the SHA-256 message digest function and an RSA private key from the specified SSL certKey object.

`Parameters``:`

certkey_name- identifies the configured certKey object. Results in an Undef error if the certkey object does not exist or does not contain an RSA private key, or if the signing operation cannot complete.

`Returns:` text_t

`*PKEY_SIGN_XML` (text_t xml_pkey)

Generates a binary digital signature using the SHA-256 message digest function and an RSA private key from the specified XML element.

`Parameters``:`

xml_pkey- an expression that supplies an <RSAKeyValue> element with the private key. Example: <RSAKeyValue> <Modulus>qXm+BASPvcrGn73KfW/
mA9HWmdzigszZrSRpbAE6wHqvMIjLrOfCe/
AJjXFG9CFGUlIDIluWgvvBkUgnYU5HwLP7xlBZdTazIb652LgSdaouAVijAX3Mr6jv1rPn3t408COwdn8Lagv/
7qpjlr9/XPxtA+scLgakV8AQmGH/42c=</Modulus> <Exponent>AQAB</Exponent>"zNjysxcIJV/
J9cTpIgPp2/x1IXHT5GTH8OMuNad0qtRSLjU1QYUmmkm9QcJJAN+7h8FEXWGabySUzBrHj/
IEbw==" <DP>QavUDQLLQpnPJXtVAo6CYhxOMCd68mwTxYKKNLjmC0pd54SFHllTLPE1FZU5EjK6q3nCeijonpfH+XX
DP> <DQ>EiXOKouJzzXTQJC3TqomF7Uf81yQNxWumOqnd11kepXgyfMwyqMvLlAGEkNSEF/
Bz18R3Wv+MIZ/IC3nLBt2xQ==</DQ> <InverseQ>ocuCmz36CP+N2aGqxaU+BKD5+3RLgRq9LFhULEz2jKx0iV9r76jsAxn3sLcTYYO9eqRPy2cz74A
nw==</InverseQ> <D>fTBD773a3GzcmgVdfZlaBLpN1ux2mf5uUVrTUQf7eVFm9egm4/
tzC5A9zjC+I/oscwTH8epL3UfRLdtp05Q6pWfJBXEnGo0QmOFFBK4pLx/
5JJpPGZ69ovDFEVOUHyiCfKE/g97T4WX3us0nFe1272zwGlHarM1YYwvfeE08UdE=</D> </
RSAKeyValue> Results in an Undef error if the XML element is invalid or does not correctly specify an RSA private key, or if the signing operation cannot complete.

`Returns:` text_t

`*PKEY_VERIFY_CERTKEY` (text_t certkey_name, text_t signature)

Verifies if the input text matches the specified signature generated using the SHA-256 messge digest function and the RSA private key associated with the specified RSA public key in the X.509 certificate in the specified certKey object. Returns true if the signature is verified, false otherwise.

`Parameters``:`

certkey_name- identifies the certkey object containing an X.509 certificate holding the RSA public key.

signature- the binary signature. Results in an Undef error if the certkey object does not exist or does not contain an X.509 certificate with an RSA public key, or if the verification operation cannot complete.

`Returns:` bool_at

`*PKEY_VERIFY_XML` (text_t xml_pkey, text_t signature)

Verifies if the input text matches the specified signature generated using the SHA-256 messge digest function and the RSA private key associated with the RSA public key supplied by the specified XML element. Returns true if the signature is verified, false otherwise.

`Parameters``:`

xml_pkey- an expression that supplies an <RSAKeyVAlue> element with the public key. Example: <RSAKeyValue> <Modulus>qXm+BASPvcrGn73KfW/mA9HWmdzigszZrSRpbAE6wHqvMIjLrOfCe/AJjXFG9CFGUlIDIluWgvvBkUgnYU5HwLP7xlBZdTazIb652LgSdaouAVijAX3Mr6jv1rPn3t408COwdn8Lagv/7qpjlr9/XPxtA+scLgakV8AQmGH/42c=</Modulus> <Exponent>AQAB</Exponent> </RSAKeyValue>

signature- the binary signature. Results in an Undef error if the XML element is invalid or does not correctly specify an RSA public key, or if the verification operation cannot complete.

`Returns:` bool_at

`*PREFIX` (`char` c, `uint` i)

Select a prefix of the Text. The selected prefix is the longest prefix that has at most Count (2nd argument) occurrences of character in the 1st argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

c- Character

i- Count

`Returns:` text_t

`*PREFIX` (`uint` i)

Select a prefix of the Text. The length of the prefix is equal to the number in the argument. If there aren't enough characters in the Text object then the entire Text is selected.

`Parameters``:`

i- Prefix Length

`Returns:` text_t

`*REGEX_MATCH` (`re` regex)

Returns TRUE if and only if the text contains at least one match of the regular expression argument. The match may occur anywhere within the text - if you wish to "anchor" this, use "\^" at the start of the regex and/or "$" at the end of the regex.

The regular expression has to be of the format: `re<delimiter>regular expression<same delimiter>`

The regular expression cannot be bigger than 1499 characters.

The regular expression should be acceptable by the PCRE regular expression library. Look at http://www.pcre.org/pcre.txt for documentation on the regular expression syntax. In particular, look at the pcrepattern man page.

There are some differences in the allowed syntax w.r.t PCRE syntax. Backreferences are not allowed. It is recommended not to use recursive regular expressions. The dot metacharacter matches newlines also. Unicode is not supported. SET_TEXT_MODE(IGNORECASE) overrides the (?i) internal option specified in the regular expression.

The PCRE library configuration can be seen in the system log, after executing 'nsapimgr -B" call ns_pixl_regex_show_config()"' at the shell prompt.

Some examples:

- HTTP.REQ.HOSTNAME.REGEX_MATCH(re/\[\[:alpha:\]\]+(abc){2,3}/)
- HTTP.REQ.URL.SET_TEXT_MODE(URLENCODED).REGEX_MATCH(re#(a*b+c*)#)
- HTTP.REQ.URL.REGEX_MATCH(re/a(?i)b/) matches ab and aB
- HTTP.REQ.URL.SET_TEXT_MODE(IGNORECASE).REGEX_MATCH(re/ab/) matches ab, aB, Ab and AB
- HTTP.REQ.BODY.REGEX_MATCH(re/(?ixm) (\^ab (.*) cd$) /) does a case-insensitive, multiline match where the dot metacharacter matches newline also. The regex itself can contain whitespace which will be ignored during the matching (x - extended regex).

This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

regex- Regular Expression

`Returns:` bool_at

`*REGEX_REPLACE` (`re` regex, text_t replacement, replacemode_e mode)

Selects the text that matches the given regular expression argument and replaces it with the the text given in the second argument. The third argument specifies whether the first match is only replaced when multiple matches occur in the text or all matches are replaced. The match may occur anywhere within the text - if you wish to "anchor" this, use "\^" at the start of the regex and/or "$" at the end of the regex. When the regular expression does not match the given string then the same string is returned.

For example: HTTP.RES.BODY(999).REGEX_REPLACE(re!\\bpassword:\\s*\\b!, "password: ***", ALL) will replace all occurrences of "password:" with "password: ***" This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

regex- Regular Expression

replacement- String to replace the match

mode- Mode of replacement

`Returns:` text_t

`*REGEX_SELECT` (`re` regex)

Selects the text that matches the given regular expression argument. The first match is returned when multiple matches occur in the text. The match may occur anywhere within the text - if you wish to "anchor" this, use "\^" at the start of the regex and/or "$" at the end of the regex. When the regular expression does not match the given string, a Text object of length of 0 is returned.

For example: HTTP.REQ.HEADER("via").REGEX_SELECT(re!NS-CACHE-\\d\\.\\d:\\s*\\d{1,3}!) will select "NS-CACHE-7.0: 70" This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

regex- Regular Expression

`Returns:` text_t

`*REPEAT` (`uint` i)

Produces a string which contains 'i' sequential copies of the input string.

`Parameters``:`

i- the number of times to repeat the string (0 or more)

`Returns:` text_t

`*RSHIFT` (`uint` i)

Return the Unsigned Long Value after bitwise right shifting the current number value by the argument number of bits. Note that the number of bits shifted is i modulo 64.

`Parameters``:`

i- Right Shift Length

`Returns:` unsigned_long_at

`*SET_CHAR_SET` (charset_e charset)

Set the character set to use for subsequent functions that use text.

`Parameters` (expressions not allowed) `:`

charset- Character Set

`Returns:` avp_unum_t

`*SET_TEXT_MODE` (textmode_e mode)

The mode setting of a Text object controls the behavior of many Text operations. The Text mode settings may also control the behavior of some operations in objects (like List) that build upon the Text object. IGNORECASE, NOIGNORECASE - controls whether string comparison is case sensitive or not. URLENCODED - If set then all Text operations are carried out after translating all %HH or %uHHHH encodings in the underlying byte stream. 1. %HH will be translated to the character Y where HH denotes the ascii value of character Y in hexadecimal. For example, the encoded text "http%3a/.html" will be decoded to "http:/.html" 2. %uWWHH will be translated to the character sequence YZ where WW denotes the ascii value of character Y in hexadecimal and HH denotes the ascii value of character Z in hexadecimal. For example, the encoded text

"http%u3a2f.html" and "http%u003a/.html" will both be decoded to"http:/.html" NOURLENCODED - Indicates that no percent encodings are present in the Text object. No percent decoding will be performed on the Text object. PLUS_AS_SPACE - If set then all Text operations are carried out after converting occurrences of the plus character to whitespace. For example, the text "hello+world" will be decoded to "hello world" NO_PLUS_AS_SPACE - If set, then the plus character will not be converted to whitespace in the Text object. BACKSLASH_ENCODED - If set, then all Text operations are carried out after performing the following operations: 1. \\XXX will be translated to the character Y where XXX denotes the ascii value of character Y in octal. The valid range of octal values for this type of encoding is \\0 to \\377. For example, the encoded text "http\ \72/.html" and "http\\072/.html" will both be decoded to "http:/.html" 2. \\xHH will be translated to the character Y where HH denotes the ascii value of character Y in hexadecimal. For example, the encoded text "http\\x3a/.html" will be decoded to "http:/.html" 3. \\\\uWWXX will be translated to the character sequence YZ where WW denotes the ascii value of character Y in hexadecimal and XX denotes the ascii value of character Z in hexadecimal. For example, the encoded text "http%u3a2f.html" and "http%u003a/.html" will both be decoded to"http:/.html" 4. Occurences of "\ \b", "\\n", "\\t", "\\f" and "\\r" are translated to the corresponding ascii characters. NO_BACKSLASH_ENCODED - If set, then backslash decoding will not be performed on the Text object. BAD_ENCODE_RAISE_UNDEF - If set, then UNDEF is raised if either the URLENCODED or BACKSLASH_ENCODED mode is set and a bad encoding corresponding to the specified encoding mode is encountered. NO_BAD_ENCODE_RAISE_UNDEF - If set, then UNDEF will not be raised when a bad encoding is encountered in the Text object. The Text operations operate on characters (as opposed to operating on bytes). By default a single byte represents a character using the ASCII encoding. But if URLENCODED mode is set then 3 bytes may represent a character. A PREFIX(3) operation will select the first 3 characters in the Text object. That means it may select up to 9 bytes for URLENCODED Text object. In the case of multibyte decodings as a result of %uXXXX or \\\\uXXXX, Text operations which attempt to treat the multiple decoded bytes as distinct characters are not allowed.

`Parameters` (expressions not allowed) `:`

mode- Text Mode

`Returns:` avp_unum_t

`*SKIP` (`char` c, `uint` i)

Select the Text after skipping over a prefix of the current Text. The skipped over prefix is the longest prefix that has at most Count (2nd argument) occurrences of character in the 1st argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

c- Character

i- Count

`Returns:` text_t

`*SKIP` (`uint` i)

Select the Text after skipping over a prefix in the current Text. The length of the prefix is equal to the number in the argument. If there aren't enough characters in the Text object then the entire Text is skipped over.

`Parameters` (expressions not allowed) `:`

i- Prefix Length

`Returns:` text_t

`*STARTSWITH_ANY` (text_t patset_name)

Results in Boolean TRUE value if the Text starts with any of the strings that are bound to the patset or dataset named by the string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` bool_at

`*STARTSWITH_INDEX` (text_t patset_name)

Returns the numerical index of the matching string, if the Text starts with any of the strings that are bound to the patset or dataset named by the string argument. Returns 0 if there is no match. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` num_at

`*STARTSWITH` (text_t start)

Results in Boolean TRUE value if a prefix of the Text object matches the string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

start- String

`Returns:` bool_at

`*STRIP_CHARS` (text_t s)

From the selected text remove the characters specified in the string.

For example: Say the selected text is / "foo.xyz=bar" /. Then on executing STRIP_CHARS('.=') or STRIP_CHARS('..=') the selected text will become /fooxyzbar /. Note that repeating character has same effect as it would be if it present only once. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*STRIP_END_CHARS` (text_t s)

Selects the Text after stripping off characters in the end of the current Text object.

For example: Say the selected text is / "foo.xyz=bar" /. Then on executing STRIP_END_CHARS('ar') the selected text will become /foo.xyz=b /. Note that repeating character has same effect as it would be if it present only once. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*STRIP_END_WS`

Selects the Text after stripping off white space in the end of the current Text object.

`Returns:` text_t

`*STRIP_START_CHARS` (text_t s)

Selects the Text after stripping off characters in the beginning of the current Text object.

For example: Say the selected text is / "foo.xyz=bar" /. Then on executing STRIP_START_CHARS('of') the selected text will become /.xyz=bar /. Note that repeating character has same effect as it would be if it present only once. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*STRIP_START_WS`

Selects the Text after stripping off white space in the beginning of the current Text object.

`Returns:` text_t

`*SUBSTR_ANY` (text_t patset_name)

Select any one sub-string that matches any string in the given patset or dataset. The patset cannot have strings longer than 255 characters. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` text_t

`*SUBSTR` (`uint` start, `uint` len)

Select the Text object of the given length at the given offset. Offset it 0 based. If there aren't enough characters after the offset then all the remaining characters are selected.

`Parameters``:`

start- Offset

len- Length

`Returns:` text_t

`*SUBSTR` (text_t s)

Select the first Text object that matches the input string argument. The input string cannot be bigger than 255 characters. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*SUB` (double_at i)

Return the Double Value after subtracting the argument from the current double value.

`Parameters``:`

i- Double

`Returns:` double_at

`*SUB` (ip_address_at i)

Return the Unsigned Long Value after subtracting the argument from the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*SUB` (num_at i)

Return the Unsigned Long Value after subtracting the argument from the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*SUB` (time_local_at i)

Return the Unsigned Long Value after subtracting the argument from the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*SUB` (time_at i)

Return the Unsigned Long Value after subtracting the argument from the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*SUB` (unsigned_long_at i)

Return the Unsigned Long Value after subtracting the argument from the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*SUFFIX` (`char` c, `uint` i)

Select a suffix of the Text. The selected suffix is the longest possible suffix containing at most Count (2nd arg) occurrences of the character in the 1st argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

c- Character

i- Count

`Returns:` text_t

`*SUFFIX` (`uint` i)

Select a suffix of the Text. The length of the suffix is equal to the number in the argument. If there aren't enough characters in the Text object then the entire Text is selected.

`Parameters``:`

i- Suffix Length

`Returns:` text_t

`*TO_LOWER`

Converts the selected text to lower case.

For example, the string "ABCd" is converted to "abcd"

`Returns:` text_t

`*TO_UPPER`

Converts the selected text to upper case.

For example, the string "abcD" is converted to "ABCD"

`Returns:` text_t

`*TRUNCATE` (`char` c, `uint` i)

Select the Text after truncating a suffix from the current Text object. The truncated suffix is the longest possible suffix containing at most Count (2nd arg) occurrences of the character in the 1st argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

c- Character

i- Count

`Returns:` text_t

`*TRUNCATE` (`uint` i)

Select the Text after truncating a suffix of the Text. The length of the suffix truncated is equal to the number in the argument. If there aren't enough characters in the Text then then all the characters are truncated.

`Parameters``:`

i- Suffix Length

`Returns:` text_t

`*TYPECAST_AVP_UNUM_T`

Convert text_t to avp_unum_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (avp_unum_t : In Diameter AVP based expressions can be written as DIAMETER.REQ.AVP(<avpcode>). For example Auth-Application-Id AVP (AVP code 258) can be extracted as DIAMETER.REQ.AVP(258) For few of the important AVPs we provide aliases. For example this AVP based expression can also be written as DIAMETER.REQ.AUTH_APPLICATION_ID. This expression returns either a object of class avp_t or returns a numerical value (object of class unsigned_long_at). The numerical value for this object is derived from the value in first instance of the AVP.)

`Returns:` avp_unum_t

`*TYPECAST_BOOL_AT`

Convert text_t to bool_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (bool_at : Boolean Operations)

`Returns:` bool_at

`*TYPECAST_COOKIE_T`

Convert text_t to cookie_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (cookie_t : The HTTP Cookie type provides operations for a cookie as it appears in the Set-Cookie and Set-Cookie2 header. In this type the Name-Value List operations are also available. The first delimiter is = and the element delimiter is ;. Multiple consecutive ; are treated as one. (Same as applying the method IGNORE_EMPTY_ELEMENTS on a Name-Value List.) You can use the Name-value List operations to access cookie attributes. The name comparison for all list operations is case insensitive. In this type Text operations are also available. Each cookie begins with a COOKIE_NAME=COOKIE_VALUE pair followed by zero or more semi-colon separated attribute-value pairs. If an attribute appears more than once in a cookie, the value associated with the first appearance of the attribute is returned.

Format Cookie: Cookie1=Value;Version=decimal;Value;Domain=Value;Path=Value)

`Returns:` cookie_t

`*TYPECAST_DIAMETER_FLAG_T`

Convert text_t to diameter_flag_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (diameter_flag_t : Provides operation to treat the underlying 1 byte as set of bit flags. then set/unset/test/reset_all operations can be done on flag)

`Returns:` diameter_flag_t

`*TYPECAST_DNS_DOMAINNAME_T`

Convert text_t to dns_domainname_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (dns_domainname_t : This object provides operations for parsing the DNS domain name as it appears at various places in the DNS data. The format is abc.foo.com.)

`Returns:` dns_domainname_t

`*TYPECAST_DNS_FLAG_T`

Convert text_t to dns_flag_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (dns_flag_t : Provides operations to test/set/unset a flag in dns header.)

`Returns:` dns_flag_t

`*TYPECAST_DOUBLE_AT`

Typecast the Unsigned Long Value to a Double value.

`Returns:` double_at

`*TYPECAST_DOUBLE_T` (double_format_e format)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error.)

`Parameters` (expressions not allowed) `:`

format- Format

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, double_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, ip_address_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, num_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one

or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, time_local_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, time_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, unsigned_long_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_HTTP_CACHE_CONTROL_T`

Convert text_t to http_cache_control_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_cache_control_t : This object provides for the ability to work on HTTP Cache-Control headers. The name comparison for all list operations is case insensitive.)

`Returns:` http_cache_control_t

`*TYPECAST_HTTP_CONTENT_LENGTH_T`

Convert text_t to http_content_length_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_content_length_t : The HTTP.REQ.CONTENT_LENGTH or HTTP.RES.CONTENT_LENGTH object can be treated as a HTTP Header or as a Number. The numerical value for this object is derived from the value in the last instance of the Content-Length header.)

`Returns:` http_content_length_t

`*TYPECAST_HTTP_COOKIE_T`

Convert text_t to http_cookie_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_cookie_t : This object provides operations for parsing

the HTTP cookie header. The name-value pair is derived from the value in the last instance of Cookie header. The format is Cookie : name0=value0; name1=value1; An HTTP Cookie header can have multiple occurrences. COUNT will return a Number containing how many headers of the current type exist. The name comparison for all list operations is case insensitive. The system does not keep track of more than 15 HTTP headers. The result will be undefined if there are more than 15 instances of the header.)

`Returns:` http_cookie_t

`*TYPECAST_HTTP_DATE_T`

Convert text_t to http_date_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_date_t : The HTTP.REQ.DATE or HTTP.RES.DATE object can be treated as a HTTP header or a Time object. The Time value is derived from the value in the last instance of the Date header. The date formats supported are RFC 822 (updated by RFC 1123), RFC 1036 (obsoletes RFC850) and ANSI C asctime() formats.)

`Returns:` http_date_t

`*TYPECAST_HTTP_HEADER_T` (text_t name)

Convert text_t to http_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_header_t : When typecasting a Text object to HTTP Header a header name must be provided.For example: HTTP.REQ.HEADER("MyHdr").TYPECAST_HTTP_HEADER_T("InHdr"))

`Parameters` (expressions not allowed) `:`

name- Header Name

`Returns:` http_header_t

`*TYPECAST_HTTP_HOSTNAME_T`

Convert text_t to http_hostname_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_hostname_t : This object provides operations for parsing the HTTP hostname as it appears at various places in the HTTP protocol data. The format is abc.foo.com:8080.)

`Returns:` http_hostname_t

`*TYPECAST_HTTP_METHOD_T`

Convert text_t to http_method_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_method_t : This object provides Text operations and HTTP Request Method Enum operations on the HTTP request method.)

`Returns:` http_method_t

`*TYPECAST_HTTP_SET_COOKIE_T`

Convert text_t to http_set_cookie_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_set_cookie_t : HTTP.RES.SET_COOKIE provides operations for parsing and operating on the SET-COOKIE header that is present in the HTTP response. HTTP Set-Cookie header supports Text and HTTP Header operations. For most Text operations the value in the last Set-Cookie header is selected. HTTP Set-Cookie header also supports special operations to extract cookies from the response. It is assumed that there will be only one cookie in a Set-Cookie header.)

`Returns:` http_set_cookie_t

`*TYPECAST_HTTP_URL_T`

Convert text_t to http_url_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_url_t : HTTP.REQ.URL provides operations for parsing and operating on the URL that is present in the first line of the HTTP request header. The supported format is \[<protocol>://<hostname>\]<path>?<query>. The Text object backing a HTTP URL object has the Text Mode set to URLENCODED by default.)

`Returns:` http_url_t

`*TYPECAST_HTTP_VERSION_T`

Convert text_t to http_version_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_version_t : HTTP.REQ.VERSION or HTTP.RES.VERSION provide operations to extract HTTP version information.)

`Returns:` http_version_t

`*TYPECAST_IPV6_ADDRESS_AT`

Convert text_t to ipv6_address_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ipv6_address_at : Provides operations for the 128-bit IPv6 address value. Some general information regarding IPv6 expressions: IPv6 PIXL expressions can be combined with other PIXL expressions using the '+' operator. The output is expected to be

the concatenation of the string representations of the individual PIXL expressions. No other operator other than '+' is expected to work when any of the operands is an IPv6 PIXL expression. Also, IPv6 PIXL expressions can be combined with any other type of PIXL expression except a PIXL expression that produces a bool result. In other words, if A and/or B are two IPv6 addresses, A+B should result in the string AB. When one of A or B is an IPv6 address, the other can only be a number or a string and not a boolean. Further, when A and/or B is an IPv6 address, the only operator allowed between them is '+'.

Example: Let the client source IPv6 address be ABCD:1234::ABCD. Let the server destination IPv4 address be 10.100.10.100. Then the expression CLIENT.IPV6.SRC + SERVER.IP.DST should produce the output "ABCD:1234::ABCD10.100.10.100". Similarly, CLIENT.IPV6.SRC + 5 should produce the result ABCD:1234::ABCD5)

`Returns:` ipv6_address_at

`*TYPECAST_IPV6_ADDRESS_T`

Convert text_t to ipv6_address_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ipv6_address_t : This object represents an IPv6 address present in the 1000:1001:CD10:0000:0000:89AB:4567:CDEF format.)

`Returns:` ipv6_address_t

`*TYPECAST_IPV6_SUBNET_AT`

Convert text_t to ipv6_subnet_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ipv6_subnet_at : Provides operations for the integral IPv6 subnet address value.)

`Returns:` ipv6_subnet_at

`*TYPECAST_IPV6_SUBNET_T`

Convert text_t to ipv6_subnet_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ipv6_subnet_t : This object represents an IPv6 subnet address present in the 1000:1001:CD10:0000:0000:89AB:4567:CDEF/64 format.)

`Returns:` ipv6_subnet_t

`*TYPECAST_IP_ADDRESS_AT`

Convert text_t to ip_address_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ip_address_at : Provides operations for the 32-bit integral IP address value.)

`Returns:` ip_address_at

`*TYPECAST_IP_ADDRESS_T`

Convert text_t to ip_address_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ip_address_t : Represents an IP address present in the 10.100.200.1 format.)

`Returns:` ip_address_t

`*TYPECAST_IP_OPTIONS_T`

Convert text_t to ip_options_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ip_options_t : IP protocol options)

`Returns:` ip_options_t

`*TYPECAST_IP_OPTIONS_TYPE_T`

Convert text_t to ip_options_type_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ip_options_type_t : IP Options Type)

`Returns:` ip_options_type_t

`*TYPECAST_IP_TOS_T`

Convert text_t to ip_tos_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ip_tos_t : Provides operations to TOS field in IP header.)

`Returns:` ip_tos_t

`*TYPECAST_LIST_T` (`char` sep)

Convert text_t to list_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (list_t : The character separator has to be provided when typecasting a textual context to list type. The current text mode has no effect on the character separator. For example if the current text mode is IGNORECASE and the separator is p then P will not be treated as a separator.)

`Parameters` (expressions not allowed) `:`

sep- Separator

`Returns:` list_t

`*TYPECAST_MAC_ADDRESS_AT`

Convert text_t to mac_address_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (mac_address_at : Provides operations for the 48-bit MAC address value.)

`Returns:` mac_address_at

`*TYPECAST_MAC_ADDRESS_T`

Convert text_t to mac_address_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (mac_address_t : Represents a MAC address present in the 12:34:56:78:9a:bc format.)

`Returns:` mac_address_t

`*TYPECAST_NUM_AT`

Typecast the Unsigned Long Value to a Number value.

`Returns:` num_at

`*TYPECAST_NUM_T` (num_format_e format)

Convert text_t to num_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (num_t : Treat the underlying text as a Number in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error.)

`Parameters` (expressions not allowed) `:`

format- Format

`Returns:` num_t

`*TYPECAST_NUM_T` (num_format_e format, num_at default_value)

Convert text_t to num_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (num_t : Treat the underlying text as a Number in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` num_t

`*TYPECAST_NVLIST_T` (`char` sep1, `char` sep2)

Convert text_t to nvlist_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (nvlist_t : Two character delimiters have to be provided when typecasting a Text object to a Name-Value List. The first delimited separates the name from the value. The second delimiter separates list items. For example typecast_nvlist_t('=', '&') handles a URL query string. The Text Mode has no effect on the character delimiters. For example if the current text mode is IGNORECASE and a delimiter is p then P will not be treated as a delimiter.)

`Parameters` (expressions not allowed) `:`

sep1- delimiter1

sep2- delimiter2

`Returns:` nvlist_t

`*TYPECAST_NVLIST_T` (`char` sep1, `char` sep2, `char` quote)

Convert text_t to nvlist_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (nvlist_t : Two character delimiters and quote-character have to be provided when typecasting a Text object to a Name-Value List that supports quote-character. The first delimited separates the name from the value. The second delimiter separates list items. The third value specifies the quote character. For example typecast_nvlist_t('=', ';', "") handles a name-value list separated by semi-colons that allows quoting. The quote-character specifies that the

value can occur within the quotes and the delimiters within the quote-characters should not be taken into account. The Text Mode has no effect on the character delimiters. For example if the current text mode is IGNORECASE and a delimiter is p then P will not be treated as a delimiter.)

`Parameters` (expressions not allowed) `:`

sep1- delimiter1

sep2- delimiter2

quote- quote-character.

`Returns:` nvlist_t

`*TYPECAST_PROTOCOL_BUFFER_T`

Convert text_t to protocol_buffer_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (protocol_buffer_t : gRPC Protocol Buffers interface)

`Returns:` protocol_buffer_t

`*TYPECAST_RADIUS_AVP_T`

Convert text_t to radius_avp_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (radius_avp_t : Operations that can be performed on the returned AVPs.

`Note:` An AVP can have multiple instances in a radius message. However, the system can access only the first 16 instances.

`Example:`

- To get the first value of AVP code 26 from a request, use: radius.REQ.AVP(26).VALUE(0).
- To get the fourth value of AVP code 26 from a request, use: radius.REQ.AVP(26).VALUE(3).

)

`Returns:` radius_avp_t

`*TYPECAST_RADIUS_AVP_VALUE_T`

Convert text_t to radius_avp_value_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (radius_avp_value_t : Provides operations to typecast RADIUS AVP value to Integer value or IP Address.)

`Returns:` radius_avp_value_t

`*TYPECAST_SEQ_TEXT_T`

Convert text_t to seq_text_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (seq_text_t : Represents the Text Sequence class.)

`Returns:` seq_text_t

`*TYPECAST_SERVICEPATH_T`

Convert text_t to servicepath_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (servicepath_t : Operations that can be performed on the service path.

`Example:`

- To get the name of the service path applicable to current subscriber, use: SUBSCRIBER.SERVICEPATH
- To determine If the service function is the next in the service path applicable to scubscriber, use: SUBSCRIBER.SERVICEPATH.IS_NEXT().

)

`Returns:` servicepath_t

`*TYPECAST_SIP_CALLID_HEADER_T`

Convert text_t to sip_callid_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_callid_header_t : This object provides operations for parsing the SIP callid header.)

`Returns:` sip_callid_header_t

`*TYPECAST_SIP_CONTENT_LENGTH_T`

Convert text_t to sip_content_length_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_content_length_t : The SIP.REQ.CONTENT_LENGTH or SIP.RES.CONTENT_LENGTH object can be treated as a SIP Header or as a Number. The numerical value for this object is derived from the value in the last instance of the Content-Length header.)

`Returns:` sip_content_length_t

`*TYPECAST_SIP_FROM_HEADER_T`

Convert text_t to sip_from_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_from_header_t : This object provides operations for parsing the SIP From header.)

`Returns:` sip_from_header_t

`*TYPECAST_SIP_HEADER_T` (text_t name)

Convert text_t to sip_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_header_t : When typecasting a Text object to SIP Header a header name must be provided.For example: SIP.REQ.HEADER("MyHdr").TYPECAST_SIP_HEADER_T("InHdr"))

`Parameters` (expressions not allowed) `:`

name- Header Name

`Returns:` sip_header_t

`*TYPECAST_SIP_HOSTNAME_T`

Convert text_t to sip_hostname_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_hostname_t : This object provides operations for parsing the SIP hostname as it appears at various places in the SIP protocol data. The format is abc.foo.com:5060.)

`Returns:` sip_hostname_t

`*TYPECAST_SIP_METHOD_T`

Convert text_t to sip_method_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_method_t : This object provides Text operations and SIP Request Method Enum operations on the SIP request method.)

`Returns:` sip_method_t

`*TYPECAST_SIP_TO_HEADER_T`

Convert text_t to sip_to_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_to_header_t : This object provides operations for parsing the SIP From header.)

`Returns:` sip_to_header_t

`*TYPECAST_SIP_URL_T`

Convert text_t to sip_url_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_url_t : SIP.REQ.URL provides operations for parsing and operating on the URL that is present in the first line of the SIP request header. The supported format is \[<protocol>://<hostname>\]<path>?<query>. The Text object backing a SIP URL object has the Text Mode set to URLENCODED by default.)

`Returns:` sip_url_t

`*TYPECAST_SIP_VERSION_T`

Convert text_t to sip_version_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_version_t : SIP.REQ.VERSION or SIP.RES.VERSION provide operations to extract SIP version information.)

`Returns:` sip_version_t

`*TYPECAST_SIP_VIA_HEADER_T`

Convert text_t to sip_via_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_via_header_t : This object provides operations for parsing the SIP Via header.)

`Returns:` sip_via_header_t

`*TYPECAST_SSLVPN_MODE_T`

Convert text_t to sslvpn_mode_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sslvpn_mode_t : This object provides Text operations and SSLVPN Mode Enum operations on the SSLVPN request method.)

`Returns:` sslvpn_mode_t

`*TYPECAST_SSL_TEXT_T` (text_t name)

Convert text_t to ssl_text_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ssl_text_t : Treat the underlying text object as SSL Text.)

`Parameters` (expressions not allowed) `:`

name- Name

`Returns:` ssl_text_t

`*TYPECAST_TCP_OPTIONS_T`

Convert text_t to tcp_options_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (tcp_options_t : TCP Protocol Options)

`Returns:` tcp_options_t

`*TYPECAST_TCP_OPTIONS_TYPE_T`

Convert text_t to tcp_options_type_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (tcp_options_type_t : TCP Protocol Options Type)

`Returns:` tcp_options_type_t

`*TYPECAST_TCP_REPEATER_OPTION_T`

Convert text_t to tcp_repeater_option_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (tcp_repeater_option_t : TCP Protocol Option : Repeater)

`Returns:` tcp_repeater_option_t

`*TYPECAST_TEXT_T`

Typecast the Unsigned Long Value to its string representation.

`Returns:` text_t

`*TYPECAST_TIME_AT`

Convert text_t to time_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (time_at : Treats a number value as number of seconds since GMT Jan 1 1970 0h 0m 0s.)

`Returns:` time_at

`*TYPECAST_TIME_LOCAL_AT`

Convert text_t to time_local_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (time_local_at : Treats a number value as number of seconds since GMT Jan 1 1970 0h 0m 0s as adjsuted for the local time zone.)

`Returns:` time_local_at

`*TYPECAST_TIME_T`

Convert text_t to time_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (time_t : This object treats a Text object as a date string. The formats supported are

1\. RFC822 :: Sun, 06 Nov 1994 08:49:37 GMT 2\. RFC850 :: Sunday, 06-Nov-94 08:49:37 GMT 3\. ASCTIME :: Sun Nov 6 08:49:37 1994 4\. ASCTIME like :: Sun Nov 6 08:49:37 1994 5\. ASCTIME like :: Sun Nov 06 08:49:37 1994 6\. Http Set-Cookie Expiry date :: Sun, 06-Nov-1994 08:49:37 GMT)

`Returns:` time_t

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error.)

`Parameters` (expressions not allowed) `:`

format- Format

`Returns:` unsigned_long_t

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format, ip_address_at default_value)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` unsigned_long_t

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format, unsigned_long_at default_value)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` unsigned_long_t

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format, num_at default_value)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` unsigned_long_t

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format, time_local_at default_value)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` unsigned_long_t

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format, time_at default_value)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` unsigned_long_t

`*TYPECAST_UNUM_TEXT_T`

Convert text_t to unum_text_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unum_text_t : Provides operations to treat the underlying OctectString as Binary String or unsigned long value .)

`Returns:` unum_text_t

`*TYPECAST_URL_CATEGORY_T`

Convert text_t to url_category_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (url_category_t : Retrieves URL category and attributes from an URL)

`Returns:` url_category_t

`*TYPECAST_VENDOR_SPEC_APPID_AVP_T`

Convert text_t to vendor_spec_appid_avp_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (vendor_spec_appid_avp_t : Retrieves AVPs that are nested in the grouped AVP Vendor-Specific-Application-Id (code 260). The nested AVPs are:

- Vendor-Id
- Auth-Application-Id
- Acct-Application-Id

For example, to retrieve the Auth-Application-Id AVP from the Vendor-Specific-Application-Id AVP:

- For requests: DIAMETER.REQ.VENDOR_SPECIFIC_APPLICATION_ID.AUTH_APPLICATION_ID
- For responses: DIAMETER.RES.VENDOR_SPECIFIC_APPLICATION_ID.AUTH_APPLICATION_ID

)

`Returns:` vendor_spec_appid_avp_t

`*TYPECAST_VENDOR_SPEC_RADIUS_AVP_T`

Convert text_t to vendor_spec_radius_avp_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (vendor_spec_radius_avp_t :

- Vendor-Id

To retrieve the Vendor-Id from the Vendor-Specific AVP:

- RADIUS.REQ.VENDOR_SPECIFIC.VENDORID

)

`Returns:` vendor_spec_radius_avp_t

`*UNQUOTE` (`char` c)

If selected text is quoted by character c, Remove character c from beginning and end.

For example: Say the selected text is / "foo xyz bar " /. Then on executing UNQUOTE("") the selected text will become /foo xyz bar / This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

c- Character

`Returns:` text_t

`*UNSIGNED16_STRING` (endian_e endianness)

Create an unsigned 16-bit binary string from the number.

`Parameters` (expressions not allowed) `:`

endianness- Select little or big endian

`Returns:` text_t

`*UNSIGNED32_STRING` (endian_e endianness)

Create an unsigned 32-bit binary string from the number.

`Parameters` (expressions not allowed) `:`

endianness- Select little or big endian

`Returns:` text_t

`*UNSIGNED64_STRING` (endian_e endianness)

Create an unsigned 64-bit binary string from the number.

`Parameters` (expressions not allowed) `:`

endianness- Select little or big endian

`Returns:` text_t

`*UNSIGNED8_STRING`

Create an unsigned 8-bit binary string from the number.

`Returns:` text_t

`*URLSET_MATCHES_ANY` (text_t urlset_name)

Results in Boolean TRUE value if and only if the Text matches any of the patterns that are specified in the urlset named by the string argument. The matching is case-insensitive for domains, but case-sensitive for paths. For example:

- HTTP.REQ.HOST.APPEND(HTTP.REQ.URL).URLSET_MATCHES_ANY("urlset_forbidden") returns true when the combined domain and URL matches any pattern in the urlset whose name is "urlset_forbidden".

`Parameters` (expressions not allowed) `:`

urlset_name- urlset name

`Returns:` bool_at

`*URL_CATEGORIZE` (`uint` min_reputation, `uint` max_reputation)

Returns the URL category for the supplied URL with the given minimum and maximum reputation score. Where a score of 5 is most risky and 1 is least risky. If either score is set to 0, that bound would be ignored. By specifying the reputation scores, the function will returned the category with the highest score (most risky) based on the bounds. If there was an error getting the category or if the URL is invalid then it will result in an Undef error. For example: HTTP.REQ.HOST.APPEND(HTTP.REQ.URL).URL_CATEGORIZE(0, 0) returns value when the combined domain and URL is looked up for the URL category with the highest reputation score (most risky).

`Parameters` (expressions not allowed) `:`

min_reputation- Minimum reputation score of URL category

max_reputation- Maximum reputation score of URL category

`Returns:` url_category_t

`*URL_RESERVED_CHARS_SAFE`

Converts URL reserved characters to corresponding '%XX' values and retains the rest. This is a read only operation.

```
Based on RFC3986, following are considered URL unreserved characters:

    Alpha-numeric characters: a-z, A-Z, 0-9

    Hyphen and underscore: "-", "_"

    Dot: "."

    Tilde: "~"
```

The rest are converted to %XX encoding, 'XX' is the hex-based representation of the input character. If the requirement is to encode all but URL safe characters, please consider using HTTP_URL_SAFE method.

`Returns:` text_t

`*VALUE`

Returns the value of first instance of the AVP as OctetString..

For example, lets assume the Route-Record AVP (code 282) has three instances in a request.

- Route-Record: abcd1.netscaler.com
- Route-Record: abcd2.netscaler.com
- Route-Record: abcd3.netscaler.com

To get the first instance, the expression would be: DIAMETER.REQ.AVP(282).VALUE.

Alternatively, you can use the expression: DIAMETER.REQ.AVP(282).

`Returns:` text_t

`*VALUE` (`uint` instanceno)

Returns value of an instance of the AVP.

The first instance of the AVP can be retrieved by simply using the expression: DIAMETER.REQ.AVP(266). However, subsequent instances must be retrieved using this method.

VALUE(0) retrieves the first instance, VALUE(1) retrieves the second instance, and so on.

For example, lets assume the Route-Record AVP (code 282) has three instances in a request.

- Route-Record: abcd1.netscaler.com
- Route-Record: abcd2.netscaler.com
- Route-Record: abcd3.netscaler.com

To get the second instance, the expression would be: DIAMETER.REQ.AVP(282).VALUE(1).

`Parameters` (expressions not allowed) `:`

instanceno- AVP instance number. Maximum value: 15.

`Returns:` text_t

`*VENDOR_ID`

Returns the Vendor ID if the AVP has the Vendor-Specific bit set.

`Returns:` unsigned_long_at

`*XML_DECRYPT` (text_t certKeyName)

Decrypt the selected content, which was encrypted using the W3C XML Encryption standard.

`Parameters` (expressions not allowed) `:`

certKeyName- identifies the certkey object containing the RSA private key to be used to decrypt the bulk encryption key in the selected EncryptedData element.

`Returns:` text_t

`*XML_ENCRYPT` (text_t certKeyName, encrypt_method_e method)

Encrypt the selected cleartext using the W3C XML Encryption standard.

`Parameters` (expressions not allowed) `:`

certKeyName- identifies the certkey object containing an X.509 certificate with the RSA public key to be used to encrypt the generated bulk encryption key. Note that the certKey object need not, and usually will not, include the associated RSA private key.

method- specifies the bulk encryption method (rc4, des3, aes128, aes192, or aes256) used to encrypt the content.

`Returns:` text_t

`*XML_ENCRYPT` (text_t certKeyName, encrypt_method_e method, `uint` flags)

Encrypt the selected cleartext using the W3C XML Encryption standard.

`Parameters` (expressions not allowed) `:`

certKeyName- identifies the certkey object containing an X.509 certificate with the RSA public key to be used to encrypt the generated bulk encryption key. Note that the certKey object need not, and usually will not, include the associated RSA private key.

method- specifies the bulk encryption method (rc4, des3, aes128, aes192, or aes256) used to encrypt the content.

flags- optional bit mask to specify optional elements in the EncryptedData element. These are hints to tell the receiver what private key to use to decrypt the bulk encryption key, providing information from the certKey's X.509 certificate.

- 1 - include a KeyName element with the certKeyName;
- 2 - include a KeyValue element with the RSA public key from the certificate;
- 4 - include an X509IssuerSerial element with the certificate serial number and issuer DN;
- 8 - include an X509SubjectName element with the certificate subject DN;
- 16 - include an X509Certificate element with the entire certificate;

`Returns:` text_t

`*XPATH_HTML_WITH_MARKUP` (`xpath_str` xpathex)

Applies an XPath expression to the DOM for an HTML document and returns the selected node-set or string, including markup like element tags. node-sets are converted to strings using the standard XPath string conversion routine. The selected portion of the document can be used as the target for rewrite actions.

Examples: HTTP.REQ.BODY(1000).XPATH_HTML_WITH_MARKUP(xp%//md/head/title%) returns the <title> element in the document's <head> This can be used in a rewrite action to replace or delete the <title> element.

`Parameters` (expressions not allowed) `:`

xpathex- XPath Expression

`Returns:` text_t

`*XPATH_HTML` (`xpath_bool` xpathex)

Applies an XPath expression to the DOM for an HTML document and a boolean value.

Examples: HTTP.RES.BODY(1000).XPATH_HTML(xp%boolean(/md/head/meta)%) returns true if the <meta> element exists as a child of <head> element.

`Parameters` (expressions not allowed) `:`

xpathex- XPath Expression

`Returns:` bool_at

`*XPATH_HTML` (`xpath_double` xpathex)

Applies an XPath expression to the DOM for an HTML document and a double value.

Examples: HTTP.RES.BODY(1000).XPATH_HTML(xp%number(//video/@height)%) returns the numeric value of the height attribute of the first <video> element.

`Parameters` (expressions not allowed) `:`

xpathex- XPath Expression

`Returns:` double_at

`*XPATH_HTML` (`xpath_str` xpathex)

Applies an XPath expression to the DOM for an HTML document and returns the selected node-set or string. node-sets are converted to strings using the standard XPath string conversion routine.

Examples: HTTP.REQ.BODY(1000).XPATH_HTML(xp%//img/@src%) returns the string value of the src attribute of the first

```

BINARY_ENCODING_E

Defines the binary encodings available for the ENCRYPT(), DECRYPT(), and HMAC() functions.

Enumerations

BASE64

Original PEM base64-encoding: 6 bits (0..63) enocded as one ASCII character: 0..23 = 'A'..'Z', 24..51 = 'a'..'z', 52..61 = '0'..'9', 62 = '+', 63 = '/', '=' = pad byte. Four bytes encoded as three characters. CR/LF every 64 characters.

BASE64URL

URL and Filename safe base64-encoding: same as BASE64 except 62 = '-', 63 = '_' and no CR/LFs. Pad byte? Can be used in URLs without requiring escaping.

HEX_UPPER

Hexadecimal with 0..9 = '0'..'9' and 10..15 = 'A'..'F'.

HEX_LOWER

Hexadecimal with 0..9 = '0'..'9' and 10..15 = 'a'..'f'.

HEX_COLONS

Hexadecimal with 0..9 = '0'..'9' and 10..15 = 'A'..'F'; ':' between each hex byte. Matches BLOB_TO_HEX() output format.

HEX

Hexadecmimal: For input, accepts HEX_UPPER, HEX_LOWER, and HEX_COLONS format. For output, produces HEX_LOWER format.

NONE

No encoding: input or output text is raw binary.

BOOL_AT

Boolean Operations

This topic lists the expressions that are provided by this class.

`AND` (bool_at b)

Logical AND the boolean argument with the current boolean result.

`Parameters``:`

b- Boolean

`Returns:` bool_at

`APPEND` (text_t str)

Appends the given string to the string representation of the current boolean.

`Parameters``:`

str- the string to append.

`Returns:` text_t

- `NOT`

  Logical NOT the current boolean result.

`Returns:` bool_at

`OR` (bool_at b)

Logical OR the boolean argument with the current boolean result.

`Parameters``:`

b- Boolean

`Returns:` bool_at

- `TYPECAST_TEXT_T`

  Typecast the Boolean Value to its string representation.

`Returns:` text_t

CHARSET_E

Character Set Enum

Enumerations

ASCII

UTF_8

CIPHER_T

SSL CIPHER IN CLIENT HELLO

This topic lists the expressions that are provided by this class.

`HAS_HEXCODE` (`uint` code)

Returns true if the cipher stream has the hex code passed in the argument.

`Parameters` (expressions not allowed) `:`

code- Cipher Hex Code

`Returns:` bool_at

CLIENT_HELLO_T

Client Hello SSL

This topic lists the expressions that are provided by this class.

- `ALPN`

  Operates on ALPN extension present in the client hello message.

`Returns:` alpn_t

- `CIPHERS`

  Returns the supported ciphers proposed by the client in the client hello message.

`Returns:` cipher_t

- `CLIENT_VERSION`

  Returns the version from the message-header of the client hello message.

`Returns:` num_at

- `IS_RENEGOTIATE`

  Returns true if renegotiation is initiated in ongoing SSL session, else returns false.

`Returns:` bool_at

- `IS_REUSE`

  Returns true if reuse is proposed by client, else returns false.

`Returns:` bool_at

- `IS_SCSV`

  Returns true if in client hello SCSV (Signalling Cipher Suite Value) is advertised, else returns false. SCSV prevents protocol downgrade attack.

`Returns:` bool_at

- `IS_SESSION_TICKET`

  Returns true if in client hello session ticket is advertised, else returns false.

`Returns:` bool_at

- `LENGTH`

  Returns the length in the message-header of the client hello message.

`Returns:` num_at

- `SNI`

  Returns SNI from CLIENT HELLO In the case of non-SSL transaction or error in client hello, returns an empty string.

`Returns:` ssl_text_t

CLIENT_T

Designates an expression that refers to the client. This is the starting point for access into paramters such as Ether and SSL.

This topic lists the expressions that are provided by this class.

- `ETHER`

  Operates on the ethernet protocol data associated with the current packet.

`Returns:` ether_req_protocol_t

- `INTERFACE`

  Designates an expression that refers to the ID of the network interface through which the current packet entered the Application Switch.

`Returns:` interface_req_t

- `IP`

  Operates on the IP protocol data associated with the current packet.

`Returns:` ip_req_protocol_t

- `IPV6`

  Operate on the IPv6 protocol data.

`Returns:` ipv6_req_protocol_t

- `PROXY`

  Operates on Proxy protocol data associated with current connection.

`Returns:` proxy_protocol_info_t

- `SSL`

  Operates on the SSL protocol data for the current packet.

`Returns:` ssl_req_protocol_t

- `SSLVPN`

  Operates on the SSLVPN data for the current packet.

`Returns:` sslvpn_req_protocol_t

- `TCP`

  Operate on the TCP protocol data.

`Returns:` tcp_req_protocol_t

- `TRAFFIC_DOMAIN`

  Operates on the Traffic Domain through which the current packet entered the Application Switch.

`Returns:` traffic_domain_req_t

- `UDP`

  Operates on the UDP protocol data associated with the current packet.

`Returns:` udp_req_protocol_t

- `VLAN`

  Operates on the VLAN through which the current packet entered the Application Switch.

`Returns:` vlan_req_t

- `VXLAN`

  Operates on the VXLAN through which the current packet entered the Application Switch.

`Returns:` vxlan_req_t

COOKIE_T

The HTTP Cookie type provides operations for a cookie as it appears in the Set-Cookie and Set-Cookie2 header. In this type the Name-Value List operations are also available. The first delimiter is = and the element delimiter is ;. Multiple consecutive ; are treated as one. (Same as applying the method IGNORE_EMPTY_ELEMENTS on a Name-Value List.) You can use the Name-value List operations to access cookie attributes. The name comparison for all list operations is case insensitive. In this type Text operations are also available. Each cookie begins with a COOKIE_NAME=COOKIE_VALUE pair followed by zero or more semi-colon separated attribute-value pairs. If an attribute appears more than once in a cookie, the value associated with the first appearance of the attribute is returned.

Format Cookie: Cookie1=Value;Version=decimal;Value;Domain=Value;Path=Value

This topic lists the expressions that are provided by this class.

`*Note` *: Expressions with the * symbol are inherited / promoted from text_t nvlist_at

- `DOMAIN`

  Obtain the value of Domain field of the cookie. If Multiple Domain fields are present the value associated with the first instance is returned. For eg: Set-Cookie : Customer = "ABC"; DOMAIN=".abc.com"; DOMAIN=.xyz.com then HTTP.RES.SET_COOKIE.COOKIE("CUSTOMER").DOMAIN gives .abc.com . Note that the quotes are stripped and value is returned. String of zero length is returned in the following cases: 1) If the Domain field is not present. 2) If the Value of Domain field is not present.

`Returns:` text_t

`*EXPIRES`

Obtain the Expires field of the cookie which is date string. The value of the Expires attribute can be operated upon as a Time object. The Time object supports a number of date formats. If multiple Expires fields are present then the first one is returned. If the Expires attribute is absent then Text of length zero will be returned.

`Returns:` time_t

`*PATH`

Obtain the value of Path field of the cookie, which is a '/' separated list (Multiple / are treated as single /). If Multiple path fields are present the value associated with the first instance is returned. For eg: Set-Cookie : Customer = "ABC"; PATH="/a//b/c"; PATH= "/x/y/z" then HTTP.RES.SET_COOKIE.COOKIE("CUSTOMER").PATH gives /a//b/c. HTTP.RES.SET_COOKIE.COOKIE("CUSTOMER").PATH.GET(2) gives b. Note that the quotes are stripped and value is returned. String of zero length is returned in the following cases: 1) If the Path field is not present. 2) If the value of Path field is not present.

`Returns:` list_t

`*PORT`

Obtain the value of PORT field of the cookie. Operate as a ',' separated List on the PORT component of the COOKIE. For eg: Set-Cookie : Customer = "ABC"; PATH="/a/b/c"; PORT= "80, 2580" then HTTP.RES.SET_COOKIE.COOKIE("ABC").PORT gives 80, 2580. Note that the quotes are stripped and value is returned. String of zero length is returned in the following cases: 1) If the Port field is not present. 2) If the value of Port field is not present.

`Returns:` list_t

`*TYPECAST_TEXT_T`

Convert cookie_t to text_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (text_t : Designates any piece of text.)

`Returns:` text_t

`*VERSION`

Obtain the Value of Version field of the cookie which is a decimal integer. If Multiple version fields are present the value associated with the first instance after the COOKIE name-value pair is returned. For eg: Set-Cookie : Customer = "ABC"; VERSION = "1"; VERSION = "0" then HTTP.RES.SET_COOKIE.COOKIE("CUSTOMER").VERSION gives 1. Note that the quotes are stripped and value is returned. Default numerical value zero is returned in the following cases: 1) If the version field is not present. 2) If the value of version field is not present. 3) If the version value is not a decimal number.

`Returns:` num_t

`*AFTER_REGEX` (`re` regex)

Selects the text after the portion that matches the given regular expression argument. The first match is returned when multiple matches occur in the text. The match may occur anywhere within the text - if you wish to "anchor" this, use "\^" at the start of the regex and/or "$" at the end of the regex. When the regular expression does not match the given string, a Text object of length of 0 is returned.

Example: HTTP.REQ.HEADER("etag").AFTER_REGEX(re/KX/) will select "DAPPER" from "KXDAPPER". This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

regex- Regular Expression

`Returns:` text_t

`*AFTER_STR_ANY` (text_t patset_name)

Selects the Text that is present after the first occurrence of any of the strings that are bound to the patset named by the string argument. If there is no match to any of the strings bound to the patset in the current Text object then the result Text object has 0 length. The patset cannot have strings longer than 255 characters. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` text_t

`*AFTER_STR` (text_t s)

Selects the Text that is present after the first occurrence of the string argument. If there is no match for the argument in the current Text then the result Text object has 0 length. The input string cannot be bigger than 255 characters. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*APPEND` (bool_at b)

Appends the given boolean's string representation to the current string.

`Parameters``:`

b- the boolean value to append.

`Returns:` text_t

`*APPEND` (double_at i)

Appends the given double's string representation to the current string.

`Parameters``:`

i- the double value to append.

`Returns:` text_t

`*APPEND` (ip_address_at addr)

Appends the given IPv4's string representation to the current string.

`Parameters``:`

addr- the IPv4 address to append.

`Returns:` text_t

`*APPEND` (num_at i)

Appends the given number's string representation to the current string.

`Parameters``:`

i- the number value to append.

`Returns:` text_t

`*APPEND` (time_local_at t)

Appends the given time's string representation to the current string.

`Parameters``:`

t- the time value to append.

`Returns:` text_t

`*APPEND` (time_at t)

Appends the given time's string representation to the current string.

`Parameters``:`

t- the time value to append.

`Returns:` text_t

`*APPEND` (unsigned_long_at i)

Appends the given unsigned long's string representation to the current string.

`Parameters``:`

i- the unsigned long value to append.

`Returns:` text_t

`*APPEND` (ipv6_address_at addr)

Appends the given IPv6's string representation to the current string.

`Parameters``:`

addr- the IPv6 address to append.

`Returns:` text_t

`*APPEND` (ipv6_subnet_at addr)

Appends the given IPv6 subnet's string representation to the current string.

`Parameters``:`

addr- the IPv6 subnet to append.

`Returns:` text_t

`*APPEND` (mac_address_at addr)

Appends the given MAC's string representation to the current string.

`Parameters``:`

addr- the MAC address to append.

`Returns:` text_t

`*APPEND` (text_t str)

Appends the given string to the current string.

`Parameters``:`

str- the string to append.

`Returns:` text_t

`*APPEND` (time_at t)

Appends the given time's string representation to the current string.

`Parameters``:`

t- the time value to append.

`Returns:` text_t

`*B64DECODE`

Decodes the selected text using base64 decoding.

For example, the string "TWFu" is converted to "Man"

`Returns:` text_t

`*B64ENCODE`

Encodes the selected text using base64 encoding.

For example, the string "Man" is converted to "TWFu"

`Returns:` text_t

`*BEFORE_REGEX` (`re` regex)

Selects the text before the portion that matches the given regular expression argument. The first match is returned when multiple matches occur in the text. The match may occur anywhere within the text - if you wish to "anchor" this, use "\^" at the start of the regex and/or "$" at the end of the regex. When the regular expression does not match the given string, a Text object of length of 0 is returned.

For example: HTTP.RES.HEADER("content-type").BEFORE_REGEX(re#/#) will select "text" from "text/plain". This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

regex- Regular Expression

`Returns:` text_t

`*BEFORE_STR_ANY` (text_t patset_name)

Selects the Text that is present before the first occurrence of any of the strings that are bound to the patset or datasetnamed by the string argument. If there is no match to any of the strings bound to the patset in the current Text object then the result Text object has 0 length. The patset cannot have strings longer than 255 characters. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` text_t

`*BEFORE_STR` (text_t s)

Selects the Text that is present before the first occurrence of the string argument. If there is no match for the argument in the current Text object then the result Text object has 0 length. The input string cannot be bigger than 255 characters. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*BETWEEN` (text_t start, text_t end)

Results in Boolean TRUE value if length of the Text object is greater than or equal to the sum of the Start and End argument lengths and if the prefix of the Text object matches the Start string argument and if the Suffix of the Text object matches the End string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

start- Start

end- End

`Returns:` bool_at

`*BIN_DECODE` (binary_encoding_e encoding)

Decode the encoded input into its original byte sequence. An incorrectly enooded input will result in an Undef error.

`Parameters` (expressions not allowed) `:`

encoding- specifies how the bytes are encoded.

`Returns:` text_t

`*BIN_ENCODE` (binary_encoding_e encoding)

Encode the input byte sequence. Note that BIN_ENCODE(hex_colons) is equivalent to BLOB_TO_HEX().

`Parameters` (expressions not allowed) `:`

encoding- specifies how the bytes are to be encoded.

`Returns:` text_t

`*BLOB_TO_HEX`

Convert to hexadecimal representation and select text.

For example, the byte string abc is converted to 61:62:63.

`Returns:` text_t

`*COMPARE` (text_t s)

Results in a Number Value which is the result of comparison of the input argument with the Text object. The result is greater than 0 if the Text object is lexicographically greater than the argument. The result is 0 if the Text object and the argument match. The result is less than 0 if the Text object is lexicographically lesser than the argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` num_at

`*CONTAINS_ANY` (text_t patset_name)

Results in Boolean TRUE value if the Text contains any of the strings that are bound to the patset or dataset named by the string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` bool_at

`*CONTAINS_INDEX` (text_t patset_name)

Returns the numerical index of the matching string, if the Text contains any of the strings that are bound to the patset or dataset named by the string argument. Returns 0 if there is no match. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` num_at

`*CONTAINS` (text_t s)

Results in Boolean TRUE value if the Text contains the string given in the argument. The input string cannot be bigger than 255 characters. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*COUNT`

Return a Number Value giving the number of name-value components in the list. If the last Name-Value List component is of zero length or is all spaces then it is ignored.

`Returns:` num_at

`*CRC32`

Returns a 32-bit integer computed by applying a CRC (cyclic redundancy check) function to the selected text. This is the CRC function used by Ethernet, MPEG-2, PKZIP, GZIP, PNG, and many other applications. For example, the expression to compute the CRC value of the (first 1000 bytes of the) body of an HTTP request is: HTTP.REQ.BODY(1000).CRC32

`Returns:` num_at

`*DECODE_USING_TEXT_MODE`

Decodes the selected text using the currently configured text encoding methods like URLENCODED, BACKSLASH_ENCODED, PLUS_AS_SPACE, NOURLENCODED, NO_BACKSLASH_ENCODED and NO_PLUS_AS_SPACE. Text encoding methods are set using SET_TEXT_MODE method.

`Returns:` text_t

`*DECRYPT`

Decrypt the selected base64-encoded ciphertext using the configured encryptionParams.

`Returns:` text_t

`*DECRYPT` (binary_encoding_e in_encoding)

Decrypt the selected ciphertext using the configured encryptionParams.

`Parameters` (expressions not allowed) `:`

in_encoding- specifies how the input ciphertext is encoded. If the ciphertext is not encoded as specified, causes an Undef error.

`Returns:` text_t

`*DECRYPT` (text_t encryptionKey)

Decrypt the selected base64-encoded encrypted bytes using the configured encryption key.

`Parameters` (expressions not allowed) `:`

encryptionKey- identifies the encryptionKey object to provide the cipher method, mode, padding, key, encrypted format and optional initialization vector (IV).

`Returns:` text_t

`*DECRYPT` (text_t encryptionKey, binary_encoding_e in_encoding)

Decrypt the selected base64-encoded encrypted bytes using the configured encryption key.

`Parameters` (expressions not allowed) `:`

encryptionKey- identifies the encryptionKey object to provide the cipher method, mode, padding, key, encrypted format, and optional initialization vector (IV).

in_encoding- specifies how the input ciphertext is encoded. If the ciphertext is not encoded as specified, causes an Undef error.

`Returns:` text_t

`*DIGEST` (digest_method_e method)

Returns a byte sequence computed by applying the the specified message digest method to the selected text.

`Parameters` (expressions not allowed) `:`

method- digest method to apply to the input text

`Returns:` text_t

`*ENCRYPT`

Encrypt the selected plaintext bytes using the configured encryptionParams. The resulting ciphertext is base64-encoded.

`Returns:` text_t

`*ENCRYPT` (binary_encoding_e out_encoding)

Encrypt the selected plaintext bytes using the configured encryptionParams.

`Parameters` (expressions not allowed) `:`

out_encoding- specifies how the resulting ciphertext is encoded.

`Returns:` text_t

`*ENCRYPT` (text_t encryptionKey)

Encrypt the selected cleartext bytes using the configured encryption key.

`Parameters` (expressions not allowed) `:`

encryptionKey- identifies the encryptionKey object to provide the cipher method, mode, padding, key, encrypted format and optional initialization vector (IV).

`Returns:` text_t

`*ENCRYPT` (text_t encryptionKey, binary_encoding_e out_encoding)

Encrypt the selected cleartext bytes using the configured encryption key.

`Parameters` (expressions not allowed) `:`

encryptionKey- identifies the encryptionKey object to provide the cipher method, mode, padding, key, encrypted format and optional initialization vector (IV).

out_encoding- specifies how the resulting ciphertext is encoded.

`Returns:` text_t

`*ENDSWITH_ANY` (text_t patset_name)

Results in Boolean TRUE value if the Text ends with any of the strings that are bound to the patset or dataset named by the string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` bool_at

`*ENDSWITH_INDEX` (text_t patset_name)

Returns the numerical index of the matching string, if the Text ends with any of the strings that are bound to the patset or dataset named by the string argument. Returns 0 if there is no match. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` num_at

`*ENDSWITH` (text_t end)

Results in Boolean TRUE value if a suffix of the Text object matches the string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

end- String

`Returns:` bool_at

`*EQUALS_ANY` (text_t patset_name)

Results in Boolean TRUE value if the Text equals any of the strings that are bound to the patset or dataset named by the string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` bool_at

`*EQUALS_INDEX` (text_t patset_name)

Returns the numerical index of the matching string, if the Text equals any of the strings that are bound to the patset or dataset named by the string argument. Returns 0 if there is no match. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` num_at

`*EQ` (text_t s)

Results in Boolean TRUE value if the Text object matches the input argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*GET_SIGNED16` (`uint` n, endian_e endianness)

Get the 16-bit signed binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

endianness- Select little or big endian

`Returns:` num_at

`*GET_SIGNED32` (`uint` n, endian_e endianness)

Get the 32-bit signed binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

endianness- Select little or big endian

`Returns:` num_at

`*GET_SIGNED8` (`uint` n)

Get the 8-bit signed binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

`Returns:` num_at

`*GET_UNSIGNED16` (`uint` n, endian_e endianness)

Get the 16-bit unsigned binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

endianness- Select little or big endian

`Returns:` num_at

`*GET_UNSIGNED32` (`uint` n, endian_e endianness)

Get the 32-bit unsigned binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

endianness- Select little or big endian

`Returns:` unsigned_long_at

`*GET_UNSIGNED64` (`uint` n, endian_e endianness)

Get the 64-bit unsigned binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

endianness- Select little or big endian

`Returns:` unsigned_long_at

`*GET_UNSIGNED8` (`uint` n)

Get the 8-bit unsigned binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

`Returns:` num_at

`*GET_URLSET_METADATA` (text_t urlset_name)

Returns metadata value corresponding to pattern in the urlset. The matching is case-insensitive for domains, but case-sensitive for paths. If no pattern is matched within the urlset, the return value is a NULL string. For example:

- HTTP.REQ.HOST.APPEND(HTTP.REQ.URL).GET_URLSET_METADATA("urlset_forbidden") returns value when the combined domain and URL is looked up in the urlset whose name is "urlset_forbidden".

`Parameters` (expressions not allowed) `:`

urlset_name- urlset name

`Returns:` text_t

`*GE` (text_t s)

Results in Boolean TRUE value if the Text object is greater than or equal to the input argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*GRPC`

Interprets a text_t string as a Protocol Buffer (protocol_buffer_t type). Example: HTTP.REQ.BODY(1000).GRPC.STRING(1).EQ("bookname")

`Returns:` protocol_buffer_t

`*GT` (text_t s)

Results in Boolean TRUE value if the Text object is greater than the input argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*HASH`

Returns a positive 31 bit integer value computed by applying a proprietary NetScaler hash function to the selected text. This function is not case- sensitive and ignores whitespaces. For example, applying the HASH function to two strings "Ab c" and "abc" would produce the same value. This function should not be used for security purposes; use instead the DIGEST function with one of the standard digest methods.

`Returns:` num_at

`*HMAC` (text_t hmacKey)

Returns a byte sequence computed by applying the HMAC (Hash Message Authenticastion Code) function to the selected text using the configured HMAC key.

`Parameters` (expressions not allowed) `:`

hmacKey- indentifies the hmacKey object to provide the digest (hash) method and the key.

`Returns:` text_t

`*HMAC` (text_t hmacKey, binary_encoding_e out_encoding)

Returns a byte sequence computed by applying the HMAC (Hash Message Authenticastion Code) function to the selected text using the configured HMAC key .

`Parameters` (expressions not allowed) `:`

hmacKey- indentifies the hmacKey object to provide the digest (hash) method and the key.

out_encoding- specifies how the resulting HMAC is encoded.

`Returns:` text_t

`*HTML_XML_SAFE`

Apply XML safe transform and select text.

Converts '<', '>' and '&' in the input text to '<', '>' and '&' respectively; other characters in the input are not modified. This transform safeguards against XSS based attacks. This is a read only operation.

`Returns:` text_t

`*HTTP_HEADER_SAFE`

Apply Header safe transform and select text. Converts all new line ('\\n') characters present in the input text to '%0A' so that they can safely be used in HTTP headers. This transform safeguards against response-splitting attacks. This is a read only operation.

`Returns:` text_t

`*HTTP_URL_SAFE`

Apply URL safe transform and select text. Converts URL unsafe characters to corresponding '%xx' values and retains the rest. This is a read only operation.

Based on RFC2396, following are considered URL safe characters:

Alpha-numeric characters: a-z, A-Z, 0-9

Hyphen and underscore: "-", "_"

Dot: "."

Exclamation mark: "!"

Tilde: "~"

Asterix: "*"

Single quote: "'"

Open and close parentheses: "(", ")"

Semi-colon: ";"

Colon: ":"

At symbol: "@"

Question mark: "?"

Equals: "="

Dollar: "$"

Percent: "%"

Ampersand: "&"

Plus: "+"

Comma: ","

Forward slash: ".html"

The rest are converted to %XX encoding, 'XX' is the hex-based representation of the input character. If the requirement is to encode all but URL unreserved characters, please consider using URL_RESERVED_CHARS_SAFE method.

`Returns:` text_t

`*IS_BOOL_AT`

Results in Boolean TRUE value if the Text is of boolean type.

`Returns:` bool_at

`*IS_DOUBLE_AT`

Results in Boolean TRUE value if the Text is of double data type.

`Returns:` bool_at

`*IS_IPV6_AT`

Results in Boolean TRUE value if the Text is of IPv6 data type.

`Returns:` bool_at

`*IS_IPV6_SUBNET_AT`

Results in Boolean TRUE value if the Text is of IPv6 subnet data type.

`Returns:` bool_at

`*IS_IP_AT`

Results in Boolean TRUE value if the Text is of IPv4 data type.

`Returns:` bool_at

`*IS_MAC_ADDRESS_AT`

Results in Boolean TRUE value if the Text is of mac address data type.

`Returns:` bool_at

`*IS_NUM_AT`

Results in Boolean TRUE value if the Text is of number type.

`Returns:` bool_at

`*IS_NUM_AT` (num_format_e format)

Results in Boolean TRUE value if the Text is of number type with given input base.

`Parameters` (expressions not allowed) `:`

format- number format

`Returns:` bool_at

`*IS_STRINGMAP_KEY` (text_t string_map_name)

Returns true if the string that it operates on is present in the string map. Text mode IGNORECASE, NOIGNORECASE - controls whether key lookup in string map is case sensitive or not. For example:

- HTTP.REQ.URL.IS_STRINGMAP_KEY("url_stringmap") returns true if value of HTTP.REQ.URL is present as key in the string map whose name is "url_stringmap".
- HTTP.REQ.URL.SET_TEXT_MODE(IGNORECASE). IS_STRINGMAP_KEY("url_stringmap") returns true if value of HTTP.REQ.URL is present as key in the string map whose name is "url_stringmap". Key lookup in this case is done case-insensitively.

`Parameters` (expressions not allowed) `:`

string_map_name- identifies the string map.

`Returns:` bool_at

`*IS_TIME_AT`

Results in Boolean TRUE if the Text follows any of the standard time formats given below, otherwise false. Tue, 05 Nov 1994 08:12:31 GMT RFC822 Tuesday, 05-Nov-94 08:12:31 GMT RFC850 Tue Nov 4 08:12:31 1994 asctime

`Returns:` bool_at

`*IS_UNSIGNED_LONG_AT`

Results in Boolean TRUE value if the Text is of unsigned long data type.

`Returns:` bool_at

`*IS_UNSIGNED_LONG_AT` (num_format_e format)

Results in Boolean TRUE value if the Text is of unsigned long data type with given input base.

`Parameters` (expressions not allowed) `:`

format- number format

`Returns:` bool_at

`*JWT_VERIFY_CERTKEY` (text_t certkey_name)

Verifies the signature on the input JSON Web Token (JWT), using the RSA public key in the X.509 certificate in the specified certkey object. The token has the format HEADER.PAYLOAD.SIGNATURE where

- HEADER is a base64-encoded JSON structure indicating a signature algorithm and token type, e.g.'{"alg":"RS256","typ":"JWT"}'
- PAYLOAD is a base64-encoded JSON structure with asserted claims, e.g. '{"loggedInAs":"admin","iat":1422779638}'
- SIGNATURE is the base64-encoded bytes for the signature on HEADER.PAYLOAD.

Returns true if the signature is verified for the header and payload using the specified public key; false if the signature is not verified

`Parameters``:`

certkey_name- identifies the certkey object containing an X.509 certificate holding the RSA public key. Results in an Undef error if the certkey object does not exist or does not contain an X.509 certificate with an RSA public key, if the token is not correctly formatted, or if the verification operation cannot complete.

`Returns:` bool_at

`*JWT_VERIFY_XML` (text_t xml_pkey)

Verifies the signature on the input JSON Web Token (JWT), using the RSA public key supplied by the specified XML element. The token has the format HEADER.PAYLOAD.SIGNATURE where

- HEADER is a base64-encoded JSON structure indicating a signature algorithm and token type, e.g.'{"alg":"RS256","typ":"JWT"}'
- PAYLOAD is a base64-encoded JSON structure with asserted claims, e.g. '{"loggedInAs":"admin","iat":1422779638}'
- SIGNATURE is the base64-encoded bytes for the signature on HEADER.PAYLOAD.

Returns true if the signature is verified for the header and payload using the specified public key; false if the signature is not verified

`Parameters``:`

xml_pkey- an expression that supplies an <RSAKeyValue> element with the public key. Results in an Undef error if the XML element is invalid or does not correctly specify an RSA public key, if the token is not correctly formatted, or if the verification operation cannot complete.

`Returns:` bool_at

`*LENGTH`

Results in a Number Value that is the number of characters (not bytes) in the Text object.

`Returns:` num_at

`*LE` (text_t s)

Results in Boolean TRUE value if the Text object is less than or equal to the input argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*LOCATION_LONG`

Get the location qualifier from CLIENT.IP.SRC.LOCATION.GET(n) (ISO short name) and then convert it to human readable long name. This conversion is valid only for country names. Correct Country qualifier value (number) in GET(n) is left up to the user as qualifiers are user configurable. Expression example: CLIENT.IP.SRC.LOCATION.GET(1).LOCATION_LONG For example: Data from each expression CLIENT.IP.SRC.LOCATION: NA.US.California.SantaClara.*.* CLIENT.IP.SRC.LOCATION.GET(1): US CLIENT.IP.SRC.LOCATION.GET(1).LOCATION_LONG: United States

`Returns:` text_t

`*LT` (text_t s)

Results in Boolean TRUE value if the Text object is less than the input argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*MAP_STRING_DEFAULT_TO_KEY` (text_t string_map_name)

Returns the value corresponding to the key in the string map. This is similar to the MAP_STRING method, but if the key is not present then instead of returning a null string, it returns the key itself. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

string_map_name- identifies the string map.

`Returns:` text_t

`*MAP_STRING` (text_t string_map_name)

Returns value corresponding to key in the string map. Key is the string that it is given as input. Text mode IGNORECASE, NOIGNORECASE - controls whether key lookup in string map is case sensitive or not. For example:

- HTTP.REQ.URL.MAP_STRING("url_stringmap") returns value when the value of HTTP.REQ.URL is used as key in the string map whose name is "url_stringmap".
- HTTP.REQ.URL.SET_TEXT_MODE(IGNORECASE). MAP_STRING("url_stringmap") returns value when the value of HTTP.REQ.URL is used as key in the string map whose name is "url_stringmap". Key lookup in this case is done case-insensitively.

`Parameters` (expressions not allowed) `:`

string_map_name- identifies the string map.

`Returns:` text_t

`*MARK_SAFE`

Mark the PIXL expression safe without applying any safe transform.

`Returns:` text_t

`*MAX` (text_t s)

Compares the string argument with the current string and returns the max string. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*MIN` (text_t s)

Compares the string argument with the current string and returns the min string. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*NAMES`

Extracts a list of only the names from the name-value pair list. For example the list 'a=b,c="d=e,f",g=h' will result in the list 'a,c,g'. Empty elements will be ignored.

`Returns:` list_t

`*NAME` (`uint` i)

Operate as Text on the name component of the specified name-value component in the list. The index of the name-value component given by the argument is 0-based. If the specified index is greater than the number of components then a zero length Text object is produced.

`Parameters` (expressions not allowed) `:`

i- Index

`Returns:` text_t

`*NAME_VALUE` (`uint` i)

Returns the element in the list identified by the parameter. The parameter is a 0-based index in to the list. The result is a string. If the specified index is greater than the number of components then a zero length string is produced.

`Parameters` (expressions not allowed) `:`

i- Index

`Returns:` text_t

`*NAME_VALUE` (text_t name)

Operate as Text on the name-value component in the list. The name-value component is specified by the argument by providing the name whose name-value is needed. The first component that matches the name is selected. The matching process honors the IGNORECASE and the NOIGNORECASE text modes. The URLENCODED and the NOURLENCODED text modes are ignored.

`Parameters` (expressions not allowed) `:`

name- Name

`Returns:` text_t

`*NAME_VALUE` (text_t name, `uint` i)

Operate as Text on the name-value component in the list. The name-value component is specified by the argument by providing the name whose name-value is needed. In a name-value list the same name can be repeated multiple times. The Index argument controls which occurence of the matching name-value component should be selected. The Index is 0-based. If the Index is too big then the Text object that is produced will have zero length. The matching process honors the IGNORECASE and the NOIGNORECASE text modes. The URLENCODED and the NOURLENCODED text modes are ignored.

`Parameters` (expressions not allowed) `:`

name- Name

i- Index

`Returns:` text_t

`*NE` (text_t s)

Results in Boolean TRUE value if the Text object is not equal to the input argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*NORMALIZE_URL`

Normalize URL. Normalizes a URL by doing "percent" decoding. See the description for URLENCODED in the SET_TEXT_MODE function. This performs the equivalent of SET_TEXT_MODE(URLENCODED).DECODE_USING_TEXT_MODE, except that it does not change the value of the current text mode.

`Returns:` text_t

`*PKEY_ENCRYPT_PEM_NO_PADDING` (text_t pem_pkey)

Encrypts the input text using the RSA public key provided by the PEM string and RSA_NO_PADDING padding method. The input text to be encrypted cannot be longer than the public key length minus 11 bytes for padding. For example, for a 1024-bit (128 byte) key, the input text cannot be longer than 128 - 11 = 117 bytes. An Undef error will occur if the input text is too long. A null input will also cause an Undef error. Returns the (unencoded binary) encrypted text, which is typically base-64 encoded for use in a message.

`Parameters``:`

pem_pkey- a text expression that supplies a RSA public key in the PEM format. If the text value is not a valid PEM RSA PUBLIC KEY encoding, an Undef error will occur. Example (a 1024-bit public key):

```
"-----BEGIN RSA PUBLIC KEY-----" +

"MIGJAoGBAKl5vgQEj73Kxp+9yn1v5gPR1pnc4oLM2a0kaWwBOsB6rzCIy6znwnvw" +

"CY1xRvQhRlJSAyJbloL7wZFIJ2FOR8Cz+8ZQWXU2syG+udi4EnWqLgFYowF9zK+o" +

"79az597eNPAjsHZ/C2oL/+6qY5a/f1z8bQPrHC4GpFfAEJhh/+NnAgMBAAE=" +

"-----END RSA PUBLIC KEY-----"
```

`Returns:` text_t

`*PKEY_ENCRYPT_PEM` (text_t pem_pkey)

Encrypts the input text using the RSA public key provided by the PEM string and the RSA_PKCS1_PADDING padding method. The input text to be encrypted cannot be longer than the public key length minus 11 bytes for padding. For example, for a 1024-bit (128 byte) key, the input text cannot be longer than 128 - 11 = 117 bytes. An Undef error will occur if the input text is too long. A null input will also cause an Undef error. Returns the (unencoded binary) encrypted text, which is typically base-64 encoded for use in a message.

`Parameters``:`

pem_pkey- a text expression that supplies a RSA public key in the PEM format. If the text value is not a valid PEM RSA PUBLIC KEY encoding, an Undef error will occur. Example (a 1024-bit public key):

```
"-----BEGIN RSA PUBLIC KEY-----" +

"MIGJAoGBAKl5vgQEj73Kxp+9yn1v5gPR1pnc4oLM2a0kaWwBOsB6rzCIy6znwnvw" +

"CY1xRvQhRlJSAyJbloL7wZFIJ2FOR8Cz+8ZQWXU2syG+udi4EnWqLgFYowF9zK+o" +

"79az597eNPAjsHZ/C2oL/+6qY5a/f1z8bQPrHC4GpFfAEJhh/+NnAgMBAAE=" +

"-----END RSA PUBLIC KEY-----"
```

`Returns:` text_t

`*PKEY_SIGN_CERTKEY` (text_t certkey_name)

Generates a binary digital signature using the SHA-256 message digest function and an RSA private key from the specified SSL certKey object.

`Parameters``:`

certkey_name- identifies the configured certKey object. Results in an Undef error if the certkey object does not exist or does not contain an RSA private key, or if the signing operation cannot complete.

`Returns:` text_t

`*PKEY_SIGN_XML` (text_t xml_pkey)

Generates a binary digital signature using the SHA-256 message digest function and an RSA private key from the specified XML element.

`Parameters``:`

xml_pkey- an expression that supplies an <RSAKeyValue> element with the private key. Example: <RSAKeyValue> <Modulus>qXm+BASPvcrGn73KfW/mA9HWmdzigszZrSRpbAE6wHqvMIjLrOfCe/AJjXFG9CFGUlIDIluWgvvBkUgnYU5HwLP7xlBZdTazIb652LgSdaouAVijAX3Mr6jv1rPn3t408COwdn8Lagv/7qpjlr9/XPxtA+scLgakV8AQmGH/42c=</Modulus> <Exponent>AQAB</Exponent>"zNjysxcIJV/J9cTpIgPp2/x1IXHT5GTH8OMuNad0qtRSLjU1QYUmmkm9QcJJAN+7h8FEXWGabySUzBrHj/IEbw==" <DP>QavUDQLLQpnPJXtVAo6CYhxOMCd68mwTxYKKNLjmC0pd54SFHllTLPE1FZU5EjK6q3nCeijonpfH+XXDP> <DQ>EiXOKouJzzXTQJC3TqomF7Uf81yQNxWumOqnd11kepXgyfMwyqMvLlAGEkNSEF/Bz18R3Wv+MIZ/IC3nLBt2xQ==</DQ> <InverseQ>ocuCmz36CP+N2aGqxaU+BKD5+3RLgRq9LFhULEz2jKx0iV9r76jsAxn3sLcTYYO9eqRPy2cz74AUnw==</InverseQ> <D>fTBD773a3GzcmgVdfZlaBLpN1ux2mf5uUVrTUQf7eVFm9egm4/tzC5A9zjC+I/oscwTH8epL3UfRLdtp05Q6pWfJBXEnGo0QmOFFBK4pLx/5JJpPGZ69ovDFEVOUHyiCfKE/g97T4WX3us0nFe1272zwGlHarM1YYwvfeE08UdE=</D> </RSAKeyValue> Results in an Undef error if the XML element is invalid or does not correctly specify an RSA private key, or if the signing operation cannot complete.

`Returns:` text_t

`*PKEY_VERIFY_CERTKEY` (text_t certkey_name, text_t signature)

Verifies if the input text matches the specified signature generated using the SHA-256 messge digest function and the RSA private key associated with the specified RSA public key in the X.509 certificate in the specified certKey object. Returns true if the signature is verified, false otherwise.

`Parameters``:`

certkey_name- identifies the certkey object containing an X.509 certificate holding the RSA public key.

signature- the binary signature. Results in an Undef error if the certkey object does not exist or does not contain an X.509 certificate with an RSA public key, or if the verification operation cannot complete.

`Returns:` bool_at

`*PKEY_VERIFY_XML` (text_t xml_pkey, text_t signature)

Verifies if the input text matches the specified signature generated using the SHA-256 messge digest function and the RSA private key associated with the RSA public key supplied by the specified XML element. Returns true if the signature is verified, false otherwise.

`Parameters``:`

xml_pkey- an expression that supplies an <RSAKeyVAlue> element with the public key. Example: <RSAKeyValue> <Modulus>qXm+BASPvcrGn73KfW/ mA9HWmdzigszZrSRpbAE6wHqvMIjLrOfCe/ AJjXFG9CFGUlIDIluWgvvBkUgnYU5HwLP7xlBZdTazIb652LgSdaouAVijAX3Mr6jv1rPn3t408COwdn8Lagv/ 7qpjlr9/XPxtA+scLgakV8AQmGH/42c=</Modulus> <Exponent>AQAB</Exponent> </ RSAKeyValue>

signature- the binary signature. Results in an Undef error if the XML element is invalid or does not correctly specify an RSA public key, or if the verification operation cannot complete.

`Returns:` bool_at

`*PREFIX` (`char` c, `uint` i)

Select a prefix of the Text. The selected prefix is the longest prefix that has at most Count (2nd argument) occurrences of character in the 1st argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

c- Character

i- Count

`Returns:` text_t

`*PREFIX` (`uint` i)

Select a prefix of the Text. The length of the prefix is equal to the number in the argument. If there aren't enough characters in the Text object then the entire Text is selected.

`Parameters``:`

i- Prefix Length

`Returns:` text_t

`*REGEX_MATCH` (`re` regex)

Returns TRUE if and only if the text contains at least one match of the regular expression argument. The match may occur anywhere within the text - if you wish to "anchor" this, use "\^" at the start of the regex and/or "$" at the end of the regex.

The regular expression has to be of the format: `re<delimiter>regular expression<same delimiter>`

The regular expression cannot be bigger than 1499 characters.

The regular expression should be acceptable by the PCRE regular expression library. Look at http://www.pcre.org/pcre.txt for documentation on the regular expression syntax. In particular, look at the pcrepattern man page.

There are some differences in the allowed syntax w.r.t PCRE syntax. Backreferences are not allowed. It is recommended not to use recursive regular expressions. The dot metacharacter matches newlines also. Unicode is not supported. SET_TEXT_MODE(IGNORECASE) overrides the (?i) internal option specified in the regular expression.

The PCRE library configuration can be seen in the system log, after executing 'nsapimgr -B" call ns_pixl_regex_show_config()"' at the shell prompt.

Some examples:

- HTTP.REQ.HOSTNAME.REGEX_MATCH(re/\[\[:alpha:\]\]+(abc){2,3}/)
- HTTP.REQ.URL.SET_TEXT_MODE(URLENCODED).REGEX_MATCH(re#(a*b+c*)#)
- HTTP.REQ.URL.REGEX_MATCH(re/a(?i)b/) matches ab and aB
- HTTP.REQ.URL.SET_TEXT_MODE(IGNORECASE).REGEX_MATCH(re/ab/) matches ab, aB, Ab and AB
- HTTP.REQ.BODY.REGEX_MATCH(re/(?ixm) (\^ab (.*) cd$) /) does a case-insensitive, multiline match where the dot metacharacter matches newline also. The regex itself can contain whitespace which will be ignored during the matching (x - extended regex).

This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

regex- Regular Expression

`Returns:` bool_at

`*REGEX_REPLACE` (`re` regex, text_t replacement, replacemode_e mode)

Selects the text that matches the given regular expression argument and replaces it with the the text given in the second argument. The third argument specifies whether the first match is only replaced when multiple matches occur in the text or all matches are replaced. The match may occur anywhere within the text - if you wish to "anchor" this, use "\^" at the start of the regex and/or "$" at the end of the regex. When the regular expression does not match the given string then the same string is returned.

For example: HTTP.RES.BODY(999).REGEX_REPLACE(re!\\bpassword:\\s*\\b!, "password: ***", ALL) will replace all occurrences of "password:" with "password: ***" This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

regex- Regular Expression

replacement- String to replace the match

mode- Mode of replacement

`Returns:` text_t

`*REGEX_SELECT` (`re` regex)

Selects the text that matches the given regular expression argument. The first match is returned when multiple matches occur in the text. The match may occur anywhere within the text - if you wish to "anchor" this, use "\^" at the start of the regex and/or "$" at the end of the regex. When the regular expression does not match the given string, a Text object of length of 0 is returned.

For example: HTTP.REQ.HEADER("via").REGEX_SELECT(re!NS-CACHE-\\d\\.\\d:\\s*\\d{1,3}!) will select "NS-CACHE-7.0: 70" This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

regex- Regular Expression

`Returns:` text_t

`*REPEAT` (`uint` i)

Produces a string which contains 'i' sequential copies of the input string.

`Parameters``:`

i- the number of times to repeat the string (0 or more)

`Returns:` text_t

`*REPLACE_ALL_VALUES` (text_t value)

Replaces all the values in each name-value pair with the specified string argument. For example, given argument string "?" the list 'a=b,c=d,e=f' will result in the name-value list 'a=?,c=?,e=?'. Quotes will be stripped from the values being replaced. Empty values will be replaced with the value provided. Empty elements will be preserved.

`Parameters` (expressions not allowed) `:`

value- value to replace existing values

`Returns:` nvlist_t

`*SET_CHAR_SET` (charset_e charset)

Set the character set to use for subsequent functions that use text.

`Parameters` (expressions not allowed) `:`

charset- Character Set

`Returns:` cookie_t

`*SET_TEXT_MODE` (textmode_e mode)

The mode setting of a Text object controls the behavior of many Text operations. The Text mode settings may also control the behavior of some operations in objects (like List) that build upon the Text object. IGNORECASE, NOIGNORECASE - controls whether string comparison is case sensitive or not. URLENCODED - If set then all Text operations are carried out after translating all %HH or %uHHHH encodings in the underlying byte stream. 1. %HH will be translated to the character Y where HH denotes the ascii value of character Y in hexadecimal. For example, the encoded text "http%3a/.html" will be decoded to "http:/.html" 2. %uWWHH will be translated to the character sequence YZ where WW denotes the ascii value of character Y in hexadecimal and HH denotes the ascii value of character Z in hexadecimal. For example, the encoded text "http%u3a2f.html" and "http%u003a/.html" will both be decoded to"http:/.html" NOURLENCODED - Indicates that no percent encodings are present in the Text object. No percent decoding will be performed on the Text object. PLUS_AS_SPACE - If set then all Text operations are carried out after converting occurrences of the plus character to whitespace. For example, the text "hello+world" will be decoded to "hello world" NO_PLUS_AS_SPACE - If set, then the plus

character will not be converted to whitespace in the Text object. BACKSLASH_ENCODED - If set, then all Text operations are carried out after performing the following operations: 1. \\XXX will be translated to the character Y where XXX denotes the ascii value of character Y in octal. The valid range of octal values for this type of encoding is \\0 to \\377. For example, the encoded text "http\ \72/.html" and "http\\072/.html" will both be decoded to "http:/.html" 2. \\xHH will be translated to the character Y where HH denotes the ascii value of character Y in hexadecimal. For example, the encoded text "http\\x3a/.html" will be decoded to "http:/.html" 3. \\\\uWWXX will be translated to the character sequence YZ where WW denotes the ascii value of character Y in hexadecimal and XX denotes the ascii value of character Z in hexadecimal. For example, the encoded text "http%u3a2f.html" and "http%u003a/.html" will both be decoded to"http:/.html" 4. Occurences of "\ \b", "\\n", "\\t", "\\f" and "\\r" are translated to the corresponding ascii characters. NO_BACKSLASH_ENCODED - If set, then backslash decoding will not be performed on the Text object. BAD_ENCODE_RAISE_UNDEF - If set, then UNDEF is raised if either the URLENCODED or BACKSLASH_ENCODED mode is set and a bad encoding corresponding to the specified encoding mode is encountered. NO_BAD_ENCODE_RAISE_UNDEF - If set, then UNDEF will not be raised when a bad encoding is encountered in the Text object. The Text operations operate on characters (as opposed to operating on bytes). By default a single byte represents a character using the ASCII encoding. But if URLENCODED mode is set then 3 bytes may represent a character. A PREFIX(3) operation will select the first 3 characters in the Text object. That means it may select up to 9 bytes for URLENCODED Text object. In the case of multibyte decodings as a result of %uXXXX or \\\\uXXXX, Text operations which attempt to treat the multiple decoded bytes as distinct characters are not allowed.

`Parameters` (expressions not allowed) `:`

mode- Text Mode

`Returns:` cookie_t

`*SKIP` (`char` c, `uint` i)

Select the Text after skipping over a prefix of the current Text. The skipped over prefix is the longest prefix that has at most Count (2nd argument) occurrences of character in the 1st argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

c- Character

i- Count

`Returns:` text_t

`*SKIP` (`uint` i)

Select the Text after skipping over a prefix in the current Text. The length of the prefix is equal to the number in the argument. If there aren't enough characters in the Text object then the entire Text is skipped over.

`Parameters` (expressions not allowed) `:`

i- Prefix Length

`Returns:` text_t

`*STARTSWITH_ANY` (text_t patset_name)

Results in Boolean TRUE value if the Text starts with any of the strings that are bound to the patset or dataset named by the string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` bool_at

`*STARTSWITH_INDEX` (text_t patset_name)

Returns the numerical index of the matching string, if the Text starts with any of the strings that are bound to the patset or dataset named by the string argument. Returns 0 if there is no match. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` num_at

`*STARTSWITH` (text_t start)

Results in Boolean TRUE value if a prefix of the Text object matches the string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

start- String

`Returns:` bool_at

`*STRIP_CHARS` (text_t s)

From the selected text remove the characters specified in the string.

For example: Say the selected text is / "foo.xyz=bar" /. Then on executing STRIP_CHARS('.=') or STRIP_CHARS('..=') the selected text will become /fooxyzbar /. Note that repeating character has same effect as it would be if it present only once. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*STRIP_END_CHARS` (text_t s)

Selects the Text after stripping off characters in the end of the current Text object.

For example: Say the selected text is / "foo.xyz=bar" /. Then on executing STRIP_END_CHARS('ar') the selected text will become /foo.xyz=b /. Note that repeating character has same effect as it would be if it present only once. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*STRIP_END_WS`

Selects the Text after stripping off white space in the end of the current Text object.

`Returns:` text_t

`*STRIP_START_CHARS` (text_t s)

Selects the Text after stripping off characters in the beginning of the current Text object.

For example: Say the selected text is / "foo.xyz=bar" /. Then on executing STRIP_START_CHARS('of') the selected text will become /.xyz=bar /. Note that repeating character has same effect as it would be if it present only once. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*STRIP_START_WS`

Selects the Text after stripping off white space in the beginning of the current Text object.

`Returns:` text_t

`*SUBSTR_ANY` (text_t patset_name)

Select any one sub-string that matches any string in the given patset or dataset. The patset cannot have strings longer than 255 characters. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` text_t

`*SUBSTR` (`uint` start, `uint` len)

Select the Text object of the given length at the given offset. Offset it 0 based. If there aren't enough characters after the offset then all the remaining characters are selected.

`Parameters``:`

start- Offset

len- Length

`Returns:` text_t

`*SUBSTR` (text_t s)

Select the first Text object that matches the input string argument. The input string cannot be bigger than 255 characters. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*SUFFIX` (`char` c, `uint` i)

Select a suffix of the Text. The selected suffix is the longest possible suffix containing at most Count (2nd arg) occurrences of the character in the 1st argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

c- Character

i- Count

`Returns:` text_t

`*SUFFIX` (`uint` i)

Select a suffix of the Text. The length of the suffix is equal to the number in the argument. If there aren't enough characters in the Text object then the entire Text is selected.

`Parameters``:`

i- Suffix Length

`Returns:` text_t

`*TO_LOWER`

Converts the selected text to lower case.

For example, the string "ABCd" is converted to "abcd"

`Returns:` text_t

`*TO_UPPER`

Converts the selected text to upper case.

For example, the string "abcD" is converted to "ABCD"

`Returns:` text_t

`*TRUNCATE` (`char` c, `uint` i)

Select the Text after truncating a suffix from the current Text object. The truncated suffix is the longest possible suffix containing at most Count (2nd arg) occurrences of the character in the 1st argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

c- Character

i- Count

`Returns:` text_t

`*TRUNCATE` (`uint` i)

Select the Text after truncating a suffix of the Text. The length of the suffix truncated is equal to the number in the argument. If there aren't enough characters in the Text then then all the characters are truncated.

`Parameters``:`

i- Suffix Length

`Returns:` text_t

`*TYPECAST_AVP_T`

Convert text_t to avp_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (avp_t : Operations that can be performed on the returned AVPs.

`Note:` An AVP can have multiple instances in a Diameter message. However, the system can access only the first 16 instances.

`Example:`

- To get the first value of AVP code 266 from a request, use: DIAMETER.REQ.AVP(266).VALUE(0).
- To get the fourth value of AVP code 266 from a request, use: DIAMETER.REQ.AVP(266).VALUE(3).

- To check if AVP code 1000 in the response has the vendor-specific bit set, use: DIAMETER.RES.AVP(1000).IS_VENDOR_SPECIFIC.

)

`Returns:` avp_t

`*TYPECAST_AVP_UNUM_T`

Convert text_t to avp_unum_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (avp_unum_t : In Diameter AVP based expressions can be written as DIAMETER.REQ.AVP(<avpcode>). For example Auth-Application-Id AVP (AVP code 258) can be extracted as DIAMETER.REQ.AVP(258) For few of the important AVPs we provide aliases. For example this AVP based expression can also be written as DIAMETER.REQ.AUTH_APPLICATION_ID. This expression returns either a object of class avp_t or returns a numerical value (object of class unsigned_long_at). The numerical value for this object is derived from the value in first instance of the AVP.)

`Returns:` avp_unum_t

`*TYPECAST_BOOL_AT`

Convert text_t to bool_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (bool_at : Boolean Operations)

`Returns:` bool_at

`*TYPECAST_COOKIE_T`

Convert text_t to cookie_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (cookie_t : The HTTP Cookie type provides operations for a cookie as it appears in the Set-Cookie and Set-Cookie2 header. In this type the Name-Value List operations are also available. The first delimiter is = and the element delimiter is ;. Multiple consecutive ; are treated as one. (Same as applying the method IGNORE_EMPTY_ELEMENTS on a Name-Value List.) You can use the Name-value List operations to access cookie attributes. The name comparison for all list operations is case insensitive. In this type Text operations are also available. Each cookie begins with a COOKIE_NAME=COOKIE_VALUE pair followed by zero or more semi-colon separated attribute-value pairs. If an attribute appears more than once in a cookie, the value associated with the first appearance of the attribute is returned.

Format Cookie: Cookie1=Value;Version=decimal;Value;Domain=Value;Path=Value)

`Returns:` cookie_t

`*TYPECAST_DIAMETER_FLAG_T`

Convert text_t to diameter_flag_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (diameter_flag_t : Provides operation to treat the underlying 1 byte as set of bit flags. then set/unset/test/reset_all operations can be done on flag)

`Returns:` diameter_flag_t

`*TYPECAST_DNS_DOMAINNAME_T`

Convert text_t to dns_domainname_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (dns_domainname_t : This object provides operations for parsing the DNS domain name as it appears at various places in the DNS data. The format is abc.foo.com.)

`Returns:` dns_domainname_t

`*TYPECAST_DNS_FLAG_T`

Convert text_t to dns_flag_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (dns_flag_t : Provides operations to test/set/unset a flag in dns header.)

`Returns:` dns_flag_t

`*TYPECAST_DOUBLE_AT`

Convert text_t to double_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_at : Double Value)

`Returns:` double_at

`*TYPECAST_DOUBLE_T` (double_format_e format)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error.)

`Parameters` (expressions not allowed) `:`

format- Format

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, double_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, ip_address_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, num_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, time_local_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, time_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one

or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, unsigned_long_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_HTTP_CACHE_CONTROL_T`

Convert text_t to http_cache_control_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_cache_control_t : This object provides for the ability to work on HTTP Cache-Control headers. The name comparison for all list operations is case insensitive.)

`Returns:` http_cache_control_t

`*TYPECAST_HTTP_CONTENT_LENGTH_T`

Convert text_t to http_content_length_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_content_length_t : The HTTP.REQ.CONTENT_LENGTH or HTTP.RES.CONTENT_LENGTH object can be treated as a

HTTP Header or as a Number. The numerical value for this object is derived from the value in the last instance of the Content-Length header.)

`Returns:` http_content_length_t

`*TYPECAST_HTTP_COOKIE_T`

Convert text_t to http_cookie_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_cookie_t : This object provides operations for parsing the HTTP cookie header. The name-value pair is derived from the value in the last instance of Cookie header. The format is Cookie : name0=value0; name1=value1; An HTTP Cookie header can have multiple occurrences. COUNT will return a Number containing how many headers of the current type exist. The name comparison for all list operations is case insensitive. The system does not keep track of more than 15 HTTP headers. The result will be undefined if there are more than 15 instances of the header.)

`Returns:` http_cookie_t

`*TYPECAST_HTTP_DATE_T`

Convert text_t to http_date_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_date_t : The HTTP.REQ.DATE or HTTP.RES.DATE object can be treated as a HTTP header or a Time object. The Time value is derived from the value in the last instance of the Date header. The date formats supported are RFC 822 (updated by RFC 1123), RFC 1036 (obsoletes RFC850) and ANSI C asctime() formats.)

`Returns:` http_date_t

`*TYPECAST_HTTP_HEADER_T` (text_t name)

Convert text_t to http_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_header_t : When typecasting a Text object to HTTP Header a header name must be provided.For example: HTTP.REQ.HEADER("MyHdr").TYPECAST_HTTP_HEADER_T("InHdr"))

`Parameters` (expressions not allowed) `:`

name- Header Name

`Returns:` http_header_t

`*TYPECAST_HTTP_HOSTNAME_T`

Convert text_t to http_hostname_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_hostname_t : This object provides operations for parsing the HTTP hostname as it appears at various places in the HTTP protocol data. The format is abc.foo.com:8080.)

`Returns:` http_hostname_t

`*TYPECAST_HTTP_METHOD_T`

Convert text_t to http_method_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_method_t : This object provides Text operations and HTTP Request Method Enum operations on the HTTP request method.)

`Returns:` http_method_t

`*TYPECAST_HTTP_SET_COOKIE_T`

Convert text_t to http_set_cookie_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_set_cookie_t : HTTP.RES.SET_COOKIE provides operations for parsing and operating on the SET-COOKIE header that is present in the HTTP response. HTTP Set-Cookie header supports Text and HTTP Header operations. For most Text operations the value in the last Set-Cookie header is selected. HTTP Set-Cookie header also supports special operations to extract cookies from the response. It is assumed that there will be only one cookie in a Set-Cookie header.)

`Returns:` http_set_cookie_t

`*TYPECAST_HTTP_URL_T`

Convert text_t to http_url_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_url_t : HTTP.REQ.URL provides operations for parsing and operating on the URL that is present in the first line of the HTTP request header. The supported format is \[<protocol>://<hostname>\]<path>?<query>. The Text object backing a HTTP URL object has the Text Mode set to URLENCODED by default.)

`Returns:` http_url_t

`*TYPECAST_HTTP_VERSION_T`

Convert text_t to http_version_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_version_t : HTTP.REQ.VERSION or HTTP.RES.VERSION provide operations to extract HTTP version information.)

`Returns:` http_version_t

`*TYPECAST_IPV6_ADDRESS_AT`

Convert text_t to ipv6_address_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ipv6_address_at : Provides operations for the 128-bit IPv6 address value. Some general information regarding IPv6 expressions: IPv6 PIXL expressions can be combined with other PIXL expressions using the '+' operator. The output is expected to be the concatenation of the string representations of the individual PIXL expressions. No other operator other than '+' is expected to work when any of the operands is an IPv6 PIXL expression. Also, IPv6 PIXL expressions can be combined with any other type of PIXL expression except a PIXL expression that produces a bool result. In other words, if A and/or B are two IPv6 addresses, A+B should result in the string AB. When one of A or B is an IPv6 address, the other can only be a number or a string and not a boolean. Further, when A and/or B is an IPv6 address, the only operator allowed between them is '+'.

Example: Let the client source IPv6 address be ABCD:1234::ABCD. Let the server destination IPv4 address be 10.100.10.100. Then the expression CLIENT.IPV6.SRC + SERVER.IP.DST should produce the output "ABCD:1234::ABCD10.100.10.100". Similarly, CLIENT.IPV6.SRC + 5 should produce the result ABCD:1234::ABCD5)

`Returns:` ipv6_address_at

`*TYPECAST_IPV6_ADDRESS_T`

Convert text_t to ipv6_address_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ipv6_address_t : This object represents an IPv6 address present in the 1000:1001:CD10:0000:0000:89AB:4567:CDEF format.)

`Returns:` ipv6_address_t

`*TYPECAST_IPV6_SUBNET_AT`

Convert text_t to ipv6_subnet_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ipv6_subnet_at : Provides operations for the integral IPv6 subnet address value.)

`Returns:` ipv6_subnet_at

`*TYPECAST_IPV6_SUBNET_T`

Convert text_t to ipv6_subnet_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ipv6_subnet_t : This object represents an IPv6 subnet address present in the 1000:1001:CD10:0000:0000:89AB:4567:CDEF/64 format.)

`Returns:` ipv6_subnet_t

`*TYPECAST_IP_ADDRESS_AT`

Convert text_t to ip_address_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ip_address_at : Provides operations for the 32-bit integral IP address value.)

`Returns:` ip_address_at

`*TYPECAST_IP_ADDRESS_T`

Convert text_t to ip_address_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ip_address_t : Represents an IP address present in the 10.100.200.1 format.)

`Returns:` ip_address_t

`*TYPECAST_IP_OPTIONS_T`

Convert text_t to ip_options_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ip_options_t : IP protocol options)

`Returns:` ip_options_t

`*TYPECAST_IP_OPTIONS_TYPE_T`

Convert text_t to ip_options_type_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ip_options_type_t : IP Options Type)

`Returns:` ip_options_type_t

`*TYPECAST_IP_TOS_T`

Convert text_t to ip_tos_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ip_tos_t : Provides operations to TOS field in IP header.)

`Returns:` ip_tos_t

`*TYPECAST_LIST_T` (`char` sep)

Convert text_t to list_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (list_t : The character separator has to be provided when typecasting a textual context to list type. The current text mode has no effect on the character separator. For example if the current text mode is IGNORECASE and the separator is p then P will not be treated as a separator.)

`Parameters` (expressions not allowed) `:`

sep- Separator

`Returns:` list_t

`*TYPECAST_MAC_ADDRESS_AT`

Convert text_t to mac_address_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (mac_address_at : Provides operations for the 48-bit MAC address value.)

`Returns:` mac_address_at

`*TYPECAST_MAC_ADDRESS_T`

Convert text_t to mac_address_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (mac_address_t : Represents a MAC address present in the 12:34:56:78:9a:bc format.)

`Returns:` mac_address_t

`*TYPECAST_NUM_AT`

Convert text_t to num_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (num_at : Number Value)

`Returns:` num_at

`*TYPECAST_NUM_T` (num_format_e format)

Convert text_t to num_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (num_t : Treat the underlying text as a Number in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and

HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error.)

`Parameters` (expressions not allowed) `:`

format- Format

`Returns:` num_t

`*TYPECAST_NUM_T` (num_format_e format, num_at default_value)

Convert text_t to num_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (num_t : Treat the underlying text as a Number in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` num_t

`*TYPECAST_NVLIST_T` (`char` sep1, `char` sep2)

Convert text_t to nvlist_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (nvlist_t : Two character delimiters have to be provided when typecasting a Text object to a Name-Value List. The first delimited separates the name from the value. The second delimiter separates list items. For example typecast_nvlist_t('=', '&') handles a URL query string. The Text Mode has no effect on the character delimiters. For example if the current text mode is IGNORECASE and a delimiter is p then P will not be treated as a delimiter.)

`Parameters` (expressions not allowed) `:`

sep1- delimiter1

sep2- delimiter2

`Returns:` nvlist_t

`*TYPECAST_NVLIST_T` (`char` sep1, `char` sep2, `char` quote)

Convert text_t to nvlist_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (nvlist_t : Two character delimiters and quote-character have to be provided when typecasting a Text object to a Name-Value List that supports quote-character. The first delimited separates the name from the value. The second delimiter separates list items. The third value specifies the quote character. For example typecast_nvlist_t('=', ';', "") handles a name-value list separated by semi-colons that allows quoting. The quote-character specifies that the value can occur within the quotes and the delimiters within the quote-characters should not be taken into account. The Text Mode has no effect on the character delimiters. For example if the current text mode is IGNORECASE and a delimiter is p then P will not be treated as a delimiter.)

`Parameters` (expressions not allowed) `:`

sep1- delimiter1

sep2- delimiter2

quote- quote-character.

`Returns:` nvlist_t

`*TYPECAST_PROTOCOL_BUFFER_T`

Convert text_t to protocol_buffer_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (protocol_buffer_t : gRPC Protocol Buffers interface)

`Returns:` protocol_buffer_t

`*TYPECAST_RADIUS_AVP_T`

Convert text_t to radius_avp_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (radius_avp_t : Operations that can be performed on the returned AVPs.

`Note:` An AVP can have multiple instances in a radius message. However, the system can access only the first 16 instances.

`Example:`

- To get the first value of AVP code 26 from a request, use: radius.REQ.AVP(26).VALUE(0).
- To get the fourth value of AVP code 26 from a request, use: radius.REQ.AVP(26).VALUE(3).

)

`Returns:` radius_avp_t

`*TYPECAST_RADIUS_AVP_VALUE_T`

Convert text_t to radius_avp_value_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (radius_avp_value_t : Provides operations to typecast RADIUS AVP value to Integer value or IP Address.)

`Returns:` radius_avp_value_t

`*TYPECAST_SEQ_TEXT_T`

Convert text_t to seq_text_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (seq_text_t : Represents the Text Sequence class.)

`Returns:` seq_text_t

`*TYPECAST_SERVICEPATH_T`

Convert text_t to servicepath_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (servicepath_t : Operations that can be performed on the service path.

`Example:`

- To get the name of the service path applicable to current subscriber, use: SUBSCRIBER.SERVICEPATH
- To determine If the service function is the next in the service path applicable to scubscriber, use: SUBSCRIBER.SERVICEPATH.IS_NEXT().

)

`Returns:` servicepath_t

`*TYPECAST_SIP_CALLID_HEADER_T`

Convert text_t to sip_callid_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_callid_header_t : This object provides operations for parsing the SIP callid header.)

`Returns:` sip_callid_header_t

`*TYPECAST_SIP_CONTENT_LENGTH_T`

Convert text_t to sip_content_length_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_content_length_t : The SIP.REQ.CONTENT_LENGTH or SIP.RES.CONTENT_LENGTH object can be treated as a SIP Header or as a Number. The numerical value for this object is derived from the value in the last instance of the Content-Length header.)

`Returns:` sip_content_length_t

`*TYPECAST_SIP_FROM_HEADER_T`

Convert text_t to sip_from_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_from_header_t : This object provides operations for parsing the SIP From header.)

`Returns:` sip_from_header_t

`*TYPECAST_SIP_HEADER_T` (text_t name)

Convert text_t to sip_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_header_t : When typecasting a Text object to SIP Header a header name must be provided.For example: SIP.REQ.HEADER("MyHdr").TYPECAST_SIP_HEADER_T("InHdr"))

`Parameters` (expressions not allowed) `:`

name- Header Name

`Returns:` sip_header_t

`*TYPECAST_SIP_HOSTNAME_T`

Convert text_t to sip_hostname_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_hostname_t : This object provides operations for parsing the SIP hostname as it appears at various places in the SIP protocol data. The format is abc.foo.com:5060.)

`Returns:` sip_hostname_t

`*TYPECAST_SIP_METHOD_T`

Convert text_t to sip_method_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_method_t : This object provides Text operations and SIP Request Method Enum operations on the SIP request method.)

`Returns:` sip_method_t

`*TYPECAST_SIP_TO_HEADER_T`

Convert text_t to sip_to_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_to_header_t : This object provides operations for parsing the SIP From header.)

`Returns:` sip_to_header_t

`*TYPECAST_SIP_URL_T`

Convert text_t to sip_url_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_url_t : SIP.REQ.URL provides operations for parsing and operating on the URL that is present in the first line of the SIP request header. The supported format is \[<protocol>://<hostname>\]<path>?<query>. The Text object backing a SIP URL object has the Text Mode set to URLENCODED by default.)

`Returns:` sip_url_t

`*TYPECAST_SIP_VERSION_T`

Convert text_t to sip_version_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_version_t : SIP.REQ.VERSION or SIP.RES.VERSION provide operations to extract SIP version information.)

`Returns:` sip_version_t

`*TYPECAST_SIP_VIA_HEADER_T`

Convert text_t to sip_via_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_via_header_t : This object provides operations for parsing the SIP Via header.)

`Returns:` sip_via_header_t

`*TYPECAST_SSLVPN_MODE_T`

Convert text_t to sslvpn_mode_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sslvpn_mode_t : This object provides Text operations and SSLVPN Mode Enum operations on the SSLVPN request method.)

`Returns:` sslvpn_mode_t

`*TYPECAST_SSL_TEXT_T` (text_t name)

Convert text_t to ssl_text_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ssl_text_t : Treat the underlying text object as SSL Text.)

`Parameters` (expressions not allowed) `:`

name- Name

`Returns:` ssl_text_t

`*TYPECAST_TCP_OPTIONS_T`

Convert text_t to tcp_options_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (tcp_options_t : TCP Protocol Options)

`Returns:` tcp_options_t

`*TYPECAST_TCP_OPTIONS_TYPE_T`

Convert text_t to tcp_options_type_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (tcp_options_type_t : TCP Protocol Options Type)

`Returns:` tcp_options_type_t

`*TYPECAST_TCP_REPEATER_OPTION_T`

Convert text_t to tcp_repeater_option_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (tcp_repeater_option_t : TCP Protocol Option : Repeater)

`Returns:` tcp_repeater_option_t

`*TYPECAST_TIME_AT`

Convert text_t to time_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (time_at : Treats a number value as number of seconds since GMT Jan 1 1970 0h 0m 0s.)

`Returns:` time_at

`*TYPECAST_TIME_LOCAL_AT`

Convert text_t to time_local_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (time_local_at : Treats a number value as number of seconds since GMT Jan 1 1970 0h 0m 0s as adjsuted for the local time zone.)

`Returns:` time_local_at

`*TYPECAST_TIME_T`

Convert text_t to time_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (time_t : This object treats a Text object as a date string. The formats supported are

1\. RFC822 :: Sun, 06 Nov 1994 08:49:37 GMT 2\. RFC850 :: Sunday, 06-Nov-94 08:49:37 GMT 3\. ASCTIME :: Sun Nov 6 08:49:37 1994 4\. ASCTIME like :: Sun Nov 6 08:49:37 1994 5\. ASCTIME like :: Sun Nov 06 08:49:37 1994 6\. Http Set-Cookie Expiry date :: Sun, 06-Nov-1994 08:49:37 GMT)

`Returns:` time_t

`*TYPECAST_UNSIGNED_LONG_AT`

Convert text_t to unsigned_long_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_at : Unsigned Long(64bit) Value)

`Returns:` unsigned_long_at

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error.)

`Parameters` (expressions not allowed) `:`

format- Format

`Returns:` unsigned_long_t

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format, ip_address_at default_value)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` unsigned_long_t

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format, unsigned_long_at default_value)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` unsigned_long_t

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format, num_at default_value)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` unsigned_long_t

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format, time_local_at default_value)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` unsigned_long_t

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format, time_at default_value)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX,

DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` unsigned_long_t

`*TYPECAST_UNUM_TEXT_T`

Convert text_t to unum_text_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unum_text_t : Provides operations to treat the underlying OctectString as Binary String or unsigned long value .)

`Returns:` unum_text_t

`*TYPECAST_URL_CATEGORY_T`

Convert text_t to url_category_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (url_category_t : Retrieves URL category and attributes from an URL)

`Returns:` url_category_t

`*TYPECAST_VENDOR_SPEC_APPID_AVP_T`

Convert text_t to vendor_spec_appid_avp_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (vendor_spec_appid_avp_t : Retrieves AVPs that are nested in the grouped AVP Vendor-Specific-Application-Id (code 260). The nested AVPs are:

- Vendor-Id
- Auth-Application-Id
- Acct-Application-Id

For example, to retrieve the Auth-Application-Id AVP from the Vendor-Specific-Application-Id AVP:

- For requests: DIAMETER.REQ.VENDOR_SPECIFIC_APPLICATION_ID.AUTH_APPLICATION_ID
- For responses: DIAMETER.RES.VENDOR_SPECIFIC_APPLICATION_ID.AUTH_APPLICATION_ID

)

`Returns:` vendor_spec_appid_avp_t

`*TYPECAST_VENDOR_SPEC_RADIUS_AVP_T`

Convert text_t to vendor_spec_radius_avp_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (vendor_spec_radius_avp_t :

- Vendor-Id

To retrieve the Vendor-Id from the Vendor-Specific AVP:

- RADIUS.REQ.VENDOR_SPECIFIC.VENDORID

)

`Returns:` vendor_spec_radius_avp_t

`*UNQUOTE` (`char` c)

If selected text is quoted by character c, Remove character c from beginning and end.

For example: Say the selected text is / "foo xyz bar " /. Then on executing UNQUOTE("") the selected text will become /foo xyz bar / This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

c- Character

`Returns:` text_t

`*URLSET_MATCHES_ANY` (text_t urlset_name)

Results in Boolean TRUE value if and only if the Text matches any of the patterns that are specified in the urlset named by the string argument. The matching is case-insensitive for domains, but case-sensitive for paths. For example:

- HTTP.REQ.HOST.APPEND(HTTP.REQ.URL).URLSET_MATCHES_ANY("urlset_forbidden") returns true when the combined domain and URL matches any pattern in the urlset whose name is "urlset_forbidden".

`Parameters` (expressions not allowed) `:`

urlset_name- urlset name

`Returns:` bool_at

`*URL_CATEGORIZE` (`uint` min_reputation, `uint` max_reputation)

Returns the URL category for the supplied URL with the given minimum and maximum reputation score. Where a score of 5 is most risky and 1 is least risky. If either score is set to 0, that bound would be ignored. By specifying the reputation scores, the function will returned the category with the highest score (most risky) based on the bounds. If there was an error getting the category or if the URL is invalid then it will result in an Undef error. For example: HTTP.REQ.HOST.APPEND(HTTP.REQ.URL).URL_CATEGORIZE(0, 0) returns value when the combined domain and URL is looked up for the URL category with the highest reputation score (most risky).

`Parameters` (expressions not allowed) `:`

min_reputation- Minimum reputation score of URL category

max_reputation- Maximum reputation score of URL category

`Returns:` url_category_t

`*URL_RESERVED_CHARS_SAFE`

Converts URL reserved characters to corresponding '%XX' values and retains the rest. This is a read only operation.

```
Based on RFC3986, following are considered URL unreserved characters:

    Alpha-numeric characters: a-z, A-Z, 0-9

    Hyphen and underscore: "-", "_"

    Dot: "."
```

```
Tilde: "~"
```

The rest are converted to %XX encoding, 'XX' is the hex-based representation of the input character. If the requirement is to encode all but URL safe characters, please consider using HTTP_URL_SAFE method.

`Returns:` text_t

`*VALUES`

Extracts a list of only the values from the name-value pair list. For example the list 'a=b,c=d,e=f' will result in the list 'b,d,f'. Note that lists do not honor the quote characters, so any nvlist_at entry that has quotes and a quoted entry includes a separator will be split at that embedded separator. Quote characters will not be stripped from the values. Empty elements and empty values will be ignored.

`Returns:` list_t

`*VALUE` (`uint` i)

Operate as Text on the value component of the specified name-value component in the list. The index of the name-value component given by the argument is 0-based. If the specified index is greater than the number of components then a zero length Text object is produced.

`Parameters` (expressions not allowed) `:`

i- Index

`Returns:` text_t

`*VALUE` (text_t name)

Operate as Text on the value component of the specified name-value component in the list. The name-value component is specified by the argument by providing the name whose value is needed. The first component that matches the name is selected. The matching process honors the IGNORECASE and the NOIGNORECASE text modes. The URLENCODED and the NOURLENCODED text modes are ignored.

`Parameters` (expressions not allowed) `:`

name- Name

`Returns:` text_t

`*VALUE` (text_t name, `uint` i)

Operate as Text on the value component of the specified name-value component in the list. The name-value component is specified by the argument by providing the name whose value is needed. In a name-value list the same name can be repeated multiple times. The Index argument controls which occurence of the matching name-value component should be selected. The Index is 0-based. If the Index is too big then the Text object that is produced will have zero length. The matching process honors the IGNORECASE and the NOIGNORECASE text modes. The URLENCODED and the NOURLENCODED text modes are ignored.

`Parameters` (expressions not allowed) `:`

name- Name

i- Index

`Returns:` text_t

`*XML_DECRYPT` (text_t certKeyName)

Decrypt the selected content, which was encrypted using the W3C XML Encryption standard.

`Parameters` (expressions not allowed) `:`

certKeyName- identifies the certkey object containing the RSA private key to be used to decrypt the bulk encryption key in the selected EncryptedData element.

`Returns:` text_t

`*XML_ENCRYPT` (text_t certKeyName, encrypt_method_e method)

Encrypt the selected cleartext using the W3C XML Encryption standard.

`Parameters` (expressions not allowed) `:`

certKeyName- identifies the certkey object containing an X.509 certificate with the RSA public key to be used to encrypt the generated bulk encryption key. Note that the certKey object need not, and usually will not, include the associated RSA private key.

method- specifies the bulk encryption method (rc4, des3, aes128, aes192, or aes256) used to encrypt the content.

`Returns:` text_t

`*XML_ENCRYPT` (text_t certKeyName, encrypt_method_e method, `uint` flags)

Encrypt the selected cleartext using the W3C XML Encryption standard.

`Parameters` (expressions not allowed) `:`

certKeyName- identifies the certkey object containing an X.509 certificate with the RSA public key to be used to encrypt the generated bulk encryption key. Note that the certKey object need not, and usually will not, include the associated RSA private key.

method- specifies the bulk encryption method (rc4, des3, aes128, aes192, or aes256) used to encrypt the content.

flags- optional bit mask to specify optional elements in the EncryptedData element. These are hints to tell the receiver what private key to use to decrypt the bulk encryption key, providing information from the certKey's X.509 certificate.

- 1 - include a KeyName element with the certKeyName;
- 2 - include a KeyValue element with the RSA public key from the certificate;
- 4 - include an X509IssuerSerial element with the certificate serial number and issuer DN;
- 8 - include an X509SubjectName element with the certificate subject DN;
- 16 - include an X509Certificate element with the entire certificate;

`Returns:` text_t

`*XPATH_HTML_WITH_MARKUP` (`xpath_str` xpathex)

Applies an XPath expression to the DOM for an HTML document and returns the selected node-set or string, including markup like element tags. node-sets are converted to strings using the standard XPath string conversion routine. The selected portion of the document can be used as the target for rewrite actions.

Examples: HTTP.REQ.BODY(1000).XPATH_HTML_WITH_MARKUP(xp%//md/head/title%) returns the <title> element in the document's <head> This can be used in a rewrite action to replace or delete the <title> element.

`Parameters` (expressions not allowed) `:`

xpathex- XPath Expression

`Returns:` text_t

`*XPATH_HTML` (`xpath_bool` xpathex)

Applies an XPath expression to the DOM for an HTML document and a boolean value.

Examples: HTTP.RES.BODY(1000).XPATH_HTML(xp%boolean(/md/head/meta)%) returns true if the <meta> element exists as a child of <head> element.

`Parameters` (expressions not allowed) `:`

xpathex- XPath Expression

`Returns:` bool_at

`*XPATH_HTML` (`xpath_double` xpathex)

Applies an XPath expression to the DOM for an HTML document and a double value.

Examples: HTTP.RES.BODY(1000).XPATH_HTML(xp%number(//video/@height)%) returns the numeric value of the height attribute of the first <video> element.

`Parameters` (expressions not allowed) `:`

xpathex- XPath Expression

`Returns:` double_at

`*XPATH_HTML` (`xpath_str` xpathex)

Applies an XPath expression to the DOM for an HTML document and returns the selected node-set or string. node-sets are converted to strings using the standard XPath string conversion routine.

Examples: HTTP.REQ.BODY(1000).XPATH_HTML(xp%//img/@src%) returns the string value of the src attribute of the first

CQA_T

Retrieves Conection Quality Analytics parameters calculated for current client.

This topic lists the expressions that are provided by this class.

- `CONGESTION_LEVEL`

  Gets detected congestion level. This returns an integer, in the range 0 to 100, that provides a measure of network congestion level. The greater the value, the the higher the detected congestion level is.

`Returns:` num_at

- `NETWORK_TYPE`

  Gets the detected network type. This should be a string of the detected nework type label (such as "2G", "3G", "4G", etc.) as defined in cqaparam configuration (parameters -net1label, -net2label and -net3label). Sets the text mode to case insensitive.

`Returns:` text_t

- `SIGNAL_QUALITY`

  Gets detected signal quality. This returns an integer, in the range 0 to 100, that provides a measure of client signal quality. The greater the value, the the better the signal quality is.

`Returns:` num_at

DIAMETER_FLAG_E

This object represents one of the diameter flags.

Enumerations

REQUEST

PROXIABLE

ERROR

RETRANSMIT

RESERVED_4

RESERVED_5

RESERVED_6

RESERVED_7

DIAMETER_FLAG_T

Provides operation to treat the underlying 1 byte as set of bit flags. then set/unset/test/reset_all operations can be done on flag

This topic lists the expressions that are provided by this class.

`*Note` *: Expressions with the * symbol are inherited / promoted from text_t

`IS_SET` (diameter_flag_e flag)

Test a flag bit (REQUEST, PROXIABLE, ERROR or RETRANSMIT) in diameter message.

`Parameters` (expressions not allowed) `:`

flag- flag bit

`Returns:` bool_at

`*RESET_ALL`

Reset flag bits in diameter message. Returns diameter_flag_t which allows further set/unset of other bits in this flag

`Returns:` diameter_flag_t

`*SET` (diameter_flag_e flag)

Set a flag bit (REQUEST, PROXIABLE, ERROR or RETRANSMIT) in diameter message. Returns diameter_flag_t which allows further set/unset of other bits in this flag

`Parameters` (expressions not allowed) `:`

flag- flag bit

`Returns:` diameter_flag_t

`*TYPECAST_TEXT_T`

Convert diameter_flag_t to text_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (text_t : Designates any piece of text.)

`Returns:` text_t

`*UNSET` (diameter_flag_e flag)

Unset a flag bit (REQUEST, PROXIABLE, ERROR or RETRANSMIT) in diameter message. Returns diameter_flag_t which allows further set/unset of other bits in this flag

`Parameters` (expressions not allowed) `:`

flag- flag bit

`Returns:` diameter_flag_t

`*AFTER_REGEX` (`re` regex)

Selects the text after the portion that matches the given regular expression argument. The first match is returned when multiple matches occur in the text. The match may occur anywhere within the text - if you wish to "anchor" this, use "\^" at the start of the regex and/or "$" at the end of the regex. When the regular expression does not match the given string, a Text object of length of 0 is returned.

Example: HTTP.REQ.HEADER("etag").AFTER_REGEX(re/KX/) will select "DAPPER" from "KXDAPPER". This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

regex- Regular Expression

`Returns:` text_t

`*AFTER_STR_ANY` (text_t patset_name)

Selects the Text that is present after the first occurrence of any of the strings that are bound to the patset named by the string argument. If there is no match to any of the strings bound to the patset in the current Text object then the result Text object has 0 length. The patset cannot have strings longer than 255 characters. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` text_t

`*AFTER_STR` (text_t s)

Selects the Text that is present after the first occurrence of the string argument. If there is no match for the argument in the current Text then the result Text object has 0 length. The input string cannot be bigger than 255 characters. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*APPEND` (bool_at b)

Appends the given boolean's string representation to the current string.

`Parameters``:`

b- the boolean value to append.

`Returns:` text_t

`*APPEND` (double_at i)

Appends the given double's string representation to the current string.

`Parameters``:`

i- the double value to append.

`Returns:` text_t

`*APPEND` (ip_address_at addr)

Appends the given IPv4's string representation to the current string.

`Parameters``:`

addr- the IPv4 address to append.

`Returns:` text_t

`*APPEND` (num_at i)

Appends the given number's string representation to the current string.

`Parameters``:`

i- the number value to append.

`Returns:` text_t

`*APPEND` (time_local_at t)

Appends the given time's string representation to the current string.

`Parameters``:`

t- the time value to append.

`Returns:` text_t

`*APPEND` (time_at t)

Appends the given time's string representation to the current string.

`Parameters``:`

t- the time value to append.

`Returns:` text_t

`*APPEND` (unsigned_long_at i)

Appends the given unsigned long's string representation to the current string.

`Parameters``:`

i- the unsigned long value to append.

`Returns:` text_t

`*APPEND` (ipv6_address_at addr)

Appends the given IPv6's string representation to the current string.

`Parameters``:`

addr- the IPv6 address to append.

`Returns:` text_t

`*APPEND` (ipv6_subnet_at addr)

Appends the given IPv6 subnet's string representation to the current string.

`Parameters``:`

addr- the IPv6 subnet to append.

`Returns:` text_t

`*APPEND` (mac_address_at addr)

Appends the given MAC's string representation to the current string.

`Parameters``:`

addr- the MAC address to append.

`Returns:` text_t

`*APPEND` (text_t str)

Appends the given string to the current string.

`Parameters``:`

str- the string to append.

`Returns:` text_t

`*APPEND` (time_at t)

Appends the given time's string representation to the current string.

`Parameters``:`

t- the time value to append.

`Returns:` text_t

`*B64DECODE`

Decodes the selected text using base64 decoding.

For example, the string "TWFu" is converted to "Man"

`Returns:` text_t

`*B64ENCODE`

Encodes the selected text using base64 encoding.

For example, the string "Man" is converted to "TWFu"

`Returns:` text_t

`*BEFORE_REGEX` (`re` regex)

Selects the text before the portion that matches the given regular expression argument. The first match is returned when multiple matches occur in the text. The match may occur anywhere within the text - if you wish to "anchor" this, use "\^" at the start of the regex and/or "$" at the end of the regex. When the regular expression does not match the given string, a Text object of length of 0 is returned.

For example: HTTP.RES.HEADER("content-type").BEFORE_REGEX(re#/#) will select "text" from "text/plain". This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

regex- Regular Expression

`Returns:` text_t

`*BEFORE_STR_ANY` (text_t patset_name)

Selects the Text that is present before the first occurrence of any of the strings that are bound to the patset or datasetnamed by the string argument. If there is no match to any of the strings bound to the patset in the current Text object then the result Text object has 0 length. The patset cannot have strings longer than 255 characters. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` text_t

`*BEFORE_STR` (text_t s)

Selects the Text that is present before the first occurrence of the string argument. If there is no match for the argument in the current Text object then the result Text object has 0 length. The input string cannot be bigger than 255 characters. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*BETWEEN` (text_t start, text_t end)

Results in Boolean TRUE value if length of the Text object is greater than or equal to the sum of the Start and End argument lengths and if the prefix of the Text object matches the Start string argument and if the Suffix of the Text object matches the End string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

start- Start

end- End

`Returns:` bool_at

`*BIN_DECODE` (binary_encoding_e encoding)

Decode the encoded input into its original byte sequence. An incorrectly enooded input will result in an Undef error.

`Parameters` (expressions not allowed) `:`

encoding- specifies how the bytes are encoded.

`Returns:` text_t

`*BIN_ENCODE` (binary_encoding_e encoding)

Encode the input byte sequence. Note that BIN_ENCODE(hex_colons) is equivalent to BLOB_TO_HEX().

`Parameters` (expressions not allowed) `:`

encoding- specifies how the bytes are to be encoded.

`Returns:` text_t

`*BLOB_TO_HEX`

Convert to hexadecimal representation and select text.

For example, the byte string abc is converted to 61:62:63.

`Returns:` text_t

`*COMPARE` (text_t s)

Results in a Number Value which is the result of comparison of the input argument with the Text object. The result is greater than 0 if the Text object is lexicographically greater than the argument. The result is 0 if the Text object and the argument match. The result is less than 0 if the Text object is lexicographically lesser than the argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` num_at

`*CONTAINS_ANY` (text_t patset_name)

Results in Boolean TRUE value if the Text contains any of the strings that are bound to the patset or dataset named by the string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed)`:`

patset_name- Pattern Set Name

`Returns:` bool_at

`*CONTAINS_INDEX` (text_t patset_name)

Returns the numerical index of the matching string, if the Text contains any of the strings that are bound to the patset or dataset named by the string argument. Returns 0 if there is no match. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed)`:`

patset_name- Pattern Set Name

`Returns:` num_at

`*CONTAINS` (text_t s)

Results in Boolean TRUE value if the Text contains the string given in the argument. The input string cannot be bigger than 255 characters. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*CRC32`

Returns a 32-bit integer computed by applying a CRC (cyclic redundancy check) function to the selected text. This is the CRC function used by Ethernet, MPEG-2, PKZIP, GZIP, PNG, and many other applications. For example, the expression to compute the CRC value of the (first 1000 bytes of the) body of an HTTP request is: HTTP.REQ.BODY(1000).CRC32

`Returns:` num_at

`*DECODE_USING_TEXT_MODE`

Decodes the selected text using the currently configured text encoding methods like URLENCODED, BACKSLASH_ENCODED, PLUS_AS_SPACE, NOURLENCODED, NO_BACKSLASH_ENCODED and NO_PLUS_AS_SPACE. Text encoding methods are set using SET_TEXT_MODE method.

`Returns:` text_t

`*DECRYPT`

Decrypt the selected base64-encoded ciphertext using the configured encryptionParams.

`Returns:` text_t

`*DECRYPT` (binary_encoding_e in_encoding)

Decrypt the selected ciphertext using the configured encryptionParams.

`Parameters` (expressions not allowed) `:`

in_encoding- specifies how the input ciphertext is encoded. If the ciphertext is not encoded as specified, causes an Undef error.

`Returns:` text_t

`*DECRYPT` (text_t encryptionKey)

Decrypt the selected base64-encoded encrypted bytes using the configured encryption key.

`Parameters` (expressions not allowed) `:`

encryptionKey- identifies the encryptionKey object to provide the cipher method, mode, padding, key, encrypted format and optional initialization vector (IV).

`Returns:` text_t

`*DECRYPT` (text_t encryptionKey, binary_encoding_e in_encoding)

Decrypt the selected base64-encoded encrypted bytes using the configured encryption key.

`Parameters` (expressions not allowed) `:`

encryptionKey- identifies the encryptionKey object to provide the cipher method, mode, padding, key, encrypted format, and optional initialization vector (IV).

in_encoding- specifies how the input ciphertext is encoded. If the ciphertext is not encoded as specified, causes an Undef error.

`Returns:` text_t

`*DIGEST` (digest_method_e method)

Returns a byte sequence computed by applying the the specified message digest method to the selected text.

`Parameters` (expressions not allowed) `:`

method- digest method to apply to the input text

`Returns:` text_t

`*ENCRYPT`

Encrypt the selected plaintext bytes using the configured encryptionParams. The resulting ciphertext is base64-encoded.

`Returns:` text_t

`*ENCRYPT` (binary_encoding_e out_encoding)

Encrypt the selected plaintext bytes using the configured encryptionParams.

`Parameters` (expressions not allowed) `:`

out_encoding- specifies how the resulting ciphertext is encoded.

`Returns:` text_t

`*ENCRYPT` (text_t encryptionKey)

Encrypt the selected cleartext bytes using the configured encryption key.

`Parameters` (expressions not allowed) `:`

encryptionKey- identifies the encryptionKey object to provide the cipher method, mode, padding, key, encrypted format and optional initialization vector (IV).

`Returns:` text_t

`*ENCRYPT` (text_t encryptionKey, binary_encoding_e out_encoding)

Encrypt the selected cleartext bytes using the configured encryption key.

`Parameters` (expressions not allowed) `:`

encryptionKey- identifies the encryptionKey object to provide the cipher method, mode, padding, key, encrypted format and optional initialization vector (IV).

out_encoding- specifies how the resulting ciphertext is encoded.

`Returns:` text_t

`*ENDSWITH_ANY` (text_t patset_name)

Results in Boolean TRUE value if the Text ends with any of the strings that are bound to the patset or dataset named by the string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` bool_at

`*ENDSWITH_INDEX` (text_t patset_name)

Returns the numerical index of the matching string, if the Text ends with any of the strings that are bound to the patset or dataset named by the string argument. Returns 0 if there is no match. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` num_at

`*ENDSWITH` (text_t end)

Results in Boolean TRUE value if a suffix of the Text object matches the string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

end- String

`Returns:` bool_at

`*EQUALS_ANY` (text_t patset_name)

Results in Boolean TRUE value if the Text equals any of the strings that are bound to the patset or dataset named by the string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` bool_at

`*EQUALS_INDEX` (text_t patset_name)

Returns the numerical index of the matching string, if the Text equals any of the strings that are bound to the patset or dataset named by the string argument. Returns 0 if there is no match. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` num_at

`*EQ` (text_t s)

Results in Boolean TRUE value if the Text object matches the input argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*GET_SIGNED16` (`uint` n, endian_e endianness)

Get the 16-bit signed binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

endianness- Select little or big endian

`Returns:` num_at

`*GET_SIGNED32` (`uint` n, endian_e endianness)

Get the 32-bit signed binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

endianness- Select little or big endian

`Returns:` num_at

`*GET_SIGNED8` (`uint` n)

Get the 8-bit signed binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

`Returns:` num_at

`*GET_UNSIGNED16` (`uint` n, endian_e endianness)

Get the 16-bit unsigned binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

endianness- Select little or big endian

`Returns:` num_at

`*GET_UNSIGNED32` (`uint` n, endian_e endianness)

Get the 32-bit unsigned binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

endianness- Select little or big endian

`Returns:` unsigned_long_at

`*GET_UNSIGNED64` (`uint` n, endian_e endianness)

Get the 64-bit unsigned binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

endianness- Select little or big endian

`Returns:` unsigned_long_at

`*GET_UNSIGNED8` (`uint` n)

Get the 8-bit unsigned binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

`Returns:` num_at

`*GET_URLSET_METADATA` (text_t urlset_name)

Returns metadata value corresponding to pattern in the urlset. The matching is case-insensitive for domains, but case-sensitive for paths. If no pattern is matched within the urlset, the return value is a NULL string. For example:

- HTTP.REQ.HOST.APPEND(HTTP.REQ.URL).GET_URLSET_METADATA("urlset_forbidden") returns value when the combined domain and URL is looked up in the urlset whose name is "urlset_forbidden".

`Parameters` (expressions not allowed) `:`

urlset_name- urlset name

`Returns:` text_t

`*GE` (text_t s)

Results in Boolean TRUE value if the Text object is greater than or equal to the input argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*GRPC`

Interprets a text_t string as a Protocol Buffer (protocol_buffer_t type). Example: HTTP.REQ.BODY(1000).GRPC.STRING(1).EQ("bookname")

`Returns:` protocol_buffer_t

`*GT` (text_t s)

Results in Boolean TRUE value if the Text object is greater than the input argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*HASH`

Returns a positive 31 bit integer value computed by applying a proprietary NetScaler hash function to the selected text. This function is not case- sensitive and ignores whitespaces. For example, applying the HASH function to two strings "Ab c" and "abc" would produce the same value. This function should not be used for security purposes; use instead the DIGEST function with one of the standard digest methods.

`Returns:` num_at

`*HMAC` (text_t hmacKey)

Returns a byte sequence computed by applying the HMAC (Hash Message Authenticastion Code) function to the selected text using the configured HMAC key.

`Parameters` (expressions not allowed) `:`

hmacKey- indentifies the hmacKey object to provide the digest (hash) method and the key.

`Returns:` text_t

`*HMAC` (text_t hmacKey, binary_encoding_e out_encoding)

Returns a byte sequence computed by applying the HMAC (Hash Message Authenticastion Code) function to the selected text using the configured HMAC key .

`Parameters` (expressions not allowed) `:`

hmacKey- indentifies the hmacKey object to provide the digest (hash) method and the key.

out_encoding- specifies how the resulting HMAC is encoded.

`Returns:` text_t

`*HTML_XML_SAFE`

Apply XML safe transform and select text.

Converts '<', '>' and '&' in the input text to '<', '>' and '&' respectively; other characters in the input are not modified. This transform safeguards against XSS based attacks. This is a read only operation.

`Returns:` text_t

`*HTTP_HEADER_SAFE`

Apply Header safe transform and select text. Converts all new line ('\\n') characters present in the input text to '%0A' so that they can safely be used in HTTP headers. This transform safeguards against response-splitting attacks. This is a read only operation.

`Returns:` text_t

`*HTTP_URL_SAFE`

Apply URL safe transform and select text. Converts URL unsafe characters to corresponding '%xx' values and retains the rest. This is a read only operation.

```
Based on RFC2396, following are considered URL safe characters:

    Alpha-numeric characters: a-z, A-Z, 0-9

    Hyphen and underscore: "-", "_"

    Dot: "."

    Exclamation mark: "!"

    Tilde: "~"

    Asterix: "&ast;"

    Single quote: "'"

    Open and close parentheses: "(", ")"

    Semi-colon: ";"

    Colon: ":"

    At symbol: "@"

    Question mark: "?"

    Equals: "="

    Dollar: "$"

    Percent: "%"
```

```
    Ampersand: "&"

    Plus: "+"

    Comma: ","

    Forward slash: ".html"
```

The rest are converted to %XX encoding, 'XX' is the hex-based representation of the input character. If the requirement is to encode all but URL unreserved characters, please consider using URL_RESERVED_CHARS_SAFE method.

`Returns:` text_t

`*IS_BOOL_AT`

Results in Boolean TRUE value if the Text is of boolean type.

`Returns:` bool_at

`*IS_DOUBLE_AT`

Results in Boolean TRUE value if the Text is of double data type.

`Returns:` bool_at

`*IS_IPV6_AT`

Results in Boolean TRUE value if the Text is of IPv6 data type.

`Returns:` bool_at

`*IS_IPV6_SUBNET_AT`

Results in Boolean TRUE value if the Text is of IPv6 subnet data type.

`Returns:` bool_at

`*IS_IP_AT`

Results in Boolean TRUE value if the Text is of IPv4 data type.

`Returns:` bool_at

`*IS_MAC_ADDRESS_AT`

Results in Boolean TRUE value if the Text is of mac address data type.

`Returns:` bool_at

`*IS_NUM_AT`

Results in Boolean TRUE value if the Text is of number type.

`Returns:` bool_at

`*IS_NUM_AT` (num_format_e format)

Results in Boolean TRUE value if the Text is of number type with given input base.

`Parameters` (expressions not allowed) `:`

format- number format

`Returns:` bool_at

`*IS_STRINGMAP_KEY` (text_t string_map_name)

Returns true if the string that it operates on is present in the string map. Text mode IGNORECASE, NOIGNORECASE - controls whether key lookup in string map is case sensitive or not. For example:

- HTTP.REQ.URL.IS_STRINGMAP_KEY("url_stringmap") returns true if value of HTTP.REQ.URL is present as key in the string map whose name is "url_stringmap".
- HTTP.REQ.URL.SET_TEXT_MODE(IGNORECASE). IS_STRINGMAP_KEY("url_stringmap") returns true if value of HTTP.REQ.URL is present as key in the string map whose name is "url_stringmap". Key lookup in this case is done case-insensitively.

`Parameters` (expressions not allowed) `:`

string_map_name- identifies the string map.

`Returns:` bool_at

`*IS_TIME_AT`

Results in Boolean TRUE if the Text follows any of the standard time formats given below, otherwise false. Tue, 05 Nov 1994 08:12:31 GMT RFC822 Tuesday, 05-Nov-94 08:12:31 GMT RFC850 Tue Nov 4 08:12:31 1994 asctime

`Returns:` bool_at

`*IS_UNSIGNED_LONG_AT`

Results in Boolean TRUE value if the Text is of unsigned long data type.

`Returns:` bool_at

`*IS_UNSIGNED_LONG_AT` (num_format_e format)

Results in Boolean TRUE value if the Text is of unsigned long data type with given input base.

`Parameters` (expressions not allowed) `:`

format- number format

`Returns:` bool_at

`*JWT_VERIFY_CERTKEY` (text_t certkey_name)

Verifies the signature on the input JSON Web Token (JWT), using the RSA public key in the X.509 certificate in the specified certkey object. The token has the format HEADER.PAYLOAD.SIGNATURE where

- HEADER is a base64-encoded JSON structure indicating a signature algorithm and token type, e.g.'{"alg":"RS256","typ":"JWT"}'
- PAYLOAD is a base64-encoded JSON structure with asserted claims, e.g. '{"loggedInAs":"admin","iat":1422779638}'
- SIGNATURE is the base64-encoded bytes for the signature on HEADER.PAYLOAD.

Returns true if the signature is verified for the header and payload using the specified public key; false if the signature is not verified

`Parameters``:`

certkey_name- identifies the certkey object containing an X.509 certificate holding the RSA public key. Results in an Undef error if the certkey object does not exist or does not contain an X.509 certificate with an RSA public key, if the token is not correctly formatted, or if the verification operation cannot complete.

`Returns:` bool_at

`*JWT_VERIFY_XML` (text_t xml_pkey)

Verifies the signature on the input JSON Web Token (JWT), using the RSA public key supplied by the specified XML element. The token has the format HEADER.PAYLOAD.SIGNATURE where

- HEADER is a base64-encoded JSON structure indicating a signature algorithm and token type, e.g.'{"alg":"RS256","typ":"JWT"}'
- PAYLOAD is a base64-encoded JSON structure with asserted claims, e.g. '{"loggedInAs":"admin","iat":1422779638}'
- SIGNATURE is the base64-encoded bytes for the signature on HEADER.PAYLOAD.

Returns true if the signature is verified for the header and payload using the specified public key; false if the signature is not verified

`Parameters``:`

xml_pkey- an expression that supplies an <RSAKeyValue> element with the public key. Results in an Undef error if the XML element is invalid or does not correctly specify an RSA public key, if the token is not correctly formatted, or if the verification operation cannot complete.

`Returns:` bool_at

`*LENGTH`

Results in a Number Value that is the number of characters (not bytes) in the Text object.

`Returns:` num_at

`*LE` (text_t s)

Results in Boolean TRUE value if the Text object is less than or equal to the input argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*LOCATION_LONG`

Get the location qualifier from CLIENT.IP.SRC.LOCATION.GET(n) (ISO short name) and then convert it to human readable long name. This conversion is valid only for country names. Correct Country qualifier value (number) in GET(n) is left up to the user as qualifiers are user configurable. Expression example: CLIENT.IP.SRC.LOCATION.GET(1).LOCATION_LONG For example: Data

from each expression CLIENT.IP.SRC.LOCATION: NA.US.California.SantaClara.*.* CLIENT.IP.SRC.LOCATION.GET(1): US CLIENT.IP.SRC.LOCATION.GET(1).LOCATION_LONG: United States

`Returns:` text_t

`*LT` (text_t s)

Results in Boolean TRUE value if the Text object is less than the input argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*MAP_STRING_DEFAULT_TO_KEY` (text_t string_map_name)

Returns the value corresponding to the key in the string map. This is similar to the MAP_STRING method, but if the key is not present then instead of returning a null string, it returns the key itself. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

string_map_name- identifies the string map.

`Returns:` text_t

`*MAP_STRING` (text_t string_map_name)

Returns value corresponding to key in the string map. Key is the string that it is given as input. Text mode IGNORECASE, NOIGNORECASE - controls whether key lookup in string map is case sensitive or not. For example:

- HTTP.REQ.URL.MAP_STRING("url_stringmap") returns value when the value of HTTP.REQ.URL is used as key in the string map whose name is "url_stringmap".
- HTTP.REQ.URL.SET_TEXT_MODE(IGNORECASE). MAP_STRING("url_stringmap") returns value when the value of HTTP.REQ.URL is used as key in the string map whose name is "url_stringmap". Key lookup in this case is done case-insensitively.

`Parameters` (expressions not allowed) `:`

string_map_name- identifies the string map.

`Returns:` text_t

`*MARK_SAFE`

Mark the PIXL expression safe without applying any safe transform.

`Returns:` text_t

`*MAX` (text_t s)

Compares the string argument with the current string and returns the max string. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*MIN` (text_t s)

Compares the string argument with the current string and returns the min string. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*NE` (text_t s)

Results in Boolean TRUE value if the Text object is not equal to the input argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*NORMALIZE_URL`

Normalize URL. Normalizes a URL by doing "percent" decoding. See the description for URLENCODED in the SET_TEXT_MODE function. This performs the equivalent of

SET_TEXT_MODE(URLENCODED).DECODE_USING_TEXT_MODE, except that it does not change the value of the current text mode.

`Returns:` text_t

`*PKEY_ENCRYPT_PEM_NO_PADDING` (text_t pem_pkey)

Encrypts the input text using the RSA public key provided by the PEM string and RSA_NO_PADDING padding method. The input text to be encrypted cannot be longer than the public key length minus 11 bytes for padding. For example, for a 1024-bit (128 byte) key, the input text cannot be longer than 128 - 11 = 117 bytes. An Undef error will occur if the input text is too long. A null input will also cause an Undef error. Returns the (unencoded binary) encrypted text, which is typically base-64 encoded for use in a message.

`Parameters``:`

pem_pkey- a text expression that supplies a RSA public key in the PEM format. If the text value is not a valid PEM RSA PUBLIC KEY encoding, an Undef error will occur. Example (a 1024-bit public key):

```
"-----BEGIN RSA PUBLIC KEY-----" +

"MIGJAoGBAKl5vgQEj73Kxp+9yn1v5gPR1pnc4oLM2a0kaWwBOsB6rzCIy6znwnvw" +

"CY1xRvQhRlJSAyJbloL7wZFIJ2FOR8Cz+8ZQWXU2syG+udi4EnWqLgFYowF9zK+o" +

"79az597eNPAjsHZ/C2oL/+6qY5a/f1z8bQPrHC4GpFfAEJhh/+NnAgMBAAE=" +

"-----END RSA PUBLIC KEY-----"
```

`Returns:` text_t

`*PKEY_ENCRYPT_PEM` (text_t pem_pkey)

Encrypts the input text using the RSA public key provided by the PEM string and the RSA_PKCS1_PADDING padding method. The input text to be encrypted cannot be longer than the public key length minus 11 bytes for padding. For example, for a 1024-bit (128 byte) key, the input text cannot be longer than 128 - 11 = 117 bytes. An Undef error will occur if the input text is too long. A null input will also cause an Undef error. Returns the (unencoded binary) encrypted text, which is typically base-64 encoded for use in a message.

`Parameters``:`

pem_pkey- a text expression that supplies a RSA public key in the PEM format. If the text value is not a valid PEM RSA PUBLIC KEY encoding, an Undef error will occur. Example (a 1024-bit public key):

```
"-----BEGIN RSA PUBLIC KEY-----" +

"MIGJAoGBAKl5vgQEj73Kxp+9yn1v5gPR1pnc4oLM2a0kaWwBOsB6rzCIy6znwnvw" +

"CY1xRvQhRlJSAyJbloL7wZFIJ2FOR8Cz+8ZQWXU2syG+udi4EnWqLgFYowF9zK+o" +

"79az597eNPAjsHZ/C2oL/+6qY5a/f1z8bQPrHC4GpFfAEJhh/+NnAgMBAAE=" +

"-----END RSA PUBLIC KEY-----"
```

`Returns:` text_t

`*PKEY_SIGN_CERTKEY` (text_t certkey_name)

Generates a binary digital signature using the SHA-256 message digest function and an RSA private key from the specified SSL certKey object.

`Parameters``:`

certkey_name- identifies the configured certKey object. Results in an Undef error if the certkey object does not exist or does not contain an RSA private key, or if the signing operation cannot complete.

`Returns:` text_t

`*PKEY_SIGN_XML` (text_t xml_pkey)

Generates a binary digital signature using the SHA-256 message digest function and an RSA private key from the specified XML element.

`Parameters``:`

xml_pkey- an expression that supplies an <RSAKeyValue> element with the private key. Example: <RSAKeyValue> <Modulus>qXm+BASPvcrGn73KfW/
mA9HWmdzigszZrSRpbAE6wHqvMIjLrOfCe/
AJjXFG9CFGUlIDIluWgvvBkUgnYU5HwLP7xlBZdTazIb652LgSdaouAVijAX3Mr6jv1rPn3t408COwdn8Lagv/
7qpjlr9/XPxtA+scLgakV8AQmGH/42c=</Modulus> <Exponent>AQAB</Exponent>"zNjysxcIJV/
J9cTpIgPp2/x1IXHT5GTH8OMuNad0qtRSLjU1QYUmmkm9QcJJAN+7h8FEXWGabySUzBrHj/

IEbw=="
<DP>QavUDQLLQpnPJXtVAo6CYhxOMCd68mwTxYKKNLjmC0pd54SFHllTLPE1FZU5EjK6q3nCeijonpfH+XX

5JJpPGZ69ovDFEVOUHyiCfKE/g97T4WX3us0nFe1272zwGlHarM1YYwvfeE08UdE=</D> </
RSAKeyValue> Results in an Undef error if the XML element is invalid or does not correctly specify an RSA private key, or if the signing operation cannot complete.

`Returns:` text_t

`*PKEY_VERIFY_CERTKEY` (text_t certkey_name, text_t signature)

Verifies if the input text matches the specified signature generated using the SHA-256 messge digest function and the RSA private key associated with the specified RSA public key in the X.509 certificate in the specified certKey object. Returns true if the signature is verified, false otherwise.

`Parameters``:`

certkey_name- identifies the certkey object containing an X.509 certificate holding the RSA public key.

signature- the binary signature. Results in an Undef error if the certkey object does not exist or does not contain an X.509 certificate with an RSA public key, or if the verification operation cannot complete.

`Returns:` bool_at

`*PKEY_VERIFY_XML` (text_t xml_pkey, text_t signature)

Verifies if the input text matches the specified signature generated using the SHA-256 messge digest function and the RSA private key associated with the RSA public key supplied by the specified XML element. Returns true if the signature is verified, false otherwise.

`Parameters``:`

xml_pkey- an expression that supplies an <RSAKeyVAlue> element with the public key. Example: <RSAKeyValue> <Modulus>qXm+BASPvcrGn73KfW/
mA9HWmdzigszZrSRpbAE6wHqvMIjLrOfCe/
AJjXFG9CFGUlIDIluWgvvBkUgnYU5HwLP7xlBZdTazIb652LgSdaouAVijAX3Mr6jv1rPn3t408COwdn8Lagv/

7qpjlr9/XPxtA+scLgakV8AQmGH/42c=</Modulus> <Exponent>AQAB</Exponent> </RSAKeyValue>

signature- the binary signature. Results in an Undef error if the XML element is invalid or does not correctly specify an RSA public key, or if the verification operation cannot complete.

`Returns:` bool_at

`*PREFIX` (`char` c, `uint` i)

Select a prefix of the Text. The selected prefix is the longest prefix that has at most Count (2nd argument) occurrences of character in the 1st argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

c- Character

i- Count

`Returns:` text_t

`*PREFIX` (`uint` i)

Select a prefix of the Text. The length of the prefix is equal to the number in the argument. If there aren't enough characters in the Text object then the entire Text is selected.

`Parameters``:`

i- Prefix Length

`Returns:` text_t

`*REGEX_MATCH` (`re` regex)

Returns TRUE if and only if the text contains at least one match of the regular expression argument. The match may occur anywhere within the text - if you wish to "anchor" this, use "\^" at the start of the regex and/or "$" at the end of the regex.

The regular expression has to be of the format: `re<delimiter>regular expression<same delimiter>`

The regular expression cannot be bigger than 1499 characters.

The regular expression should be acceptable by the PCRE regular expression library. Look at http://www.pcre.org/pcre.txt for documentation on the regular expression syntax. In particular, look at the pcrepattern man page.

There are some differences in the allowed syntax w.r.t PCRE syntax. Backreferences are not allowed. It is recommended not to use recursive regular expressions. The dot metacharacter matches newlines also. Unicode is not supported. SET_TEXT_MODE(IGNORECASE) overrides the (?i) internal option specified in the regular expression.

The PCRE library configuration can be seen in the system log, after executing 'nsapimgr -B" call ns_pixl_regex_show_config()"' at the shell prompt.

Some examples:

- HTTP.REQ.HOSTNAME.REGEX_MATCH(re/\[\[:alpha:\]\]+(abc){2,3}/)
- HTTP.REQ.URL.SET_TEXT_MODE(URLENCODED).REGEX_MATCH(re#(a*b+c*)#)
- HTTP.REQ.URL.REGEX_MATCH(re/a(?i)b/) matches ab and aB
- HTTP.REQ.URL.SET_TEXT_MODE(IGNORECASE).REGEX_MATCH(re/ab/) matches ab, aB, Ab and AB
- HTTP.REQ.BODY.REGEX_MATCH(re/(?ixm) (\^ab (.*) cd$) /) does a case-insensitive, multiline match where the dot metacharacter matches newline also. The regex itself can contain whitespace which will be ignored during the matching (x - extended regex).

This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

regex- Regular Expression

`Returns:` bool_at

`*REGEX_REPLACE` (`re` regex, text_t replacement, replacemode_e mode)

Selects the text that matches the given regular expression argument and replaces it with the the text given in the second argument. The third argument specifies whether the first match is only replaced when multiple matches occur in the text or all matches are replaced. The match may occur anywhere within the text - if you wish to "anchor" this, use "\^" at the start of the regex and/or "$" at the end of the regex. When the regular expression does not match the given string then the same string is returned.

For example: HTTP.RES.BODY(999).REGEX_REPLACE(re!\\bpassword:\\s*\\b!, "password: ***", ALL) will replace all occurrences of "password:" with "password: ***" This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

regex- Regular Expression

replacement- String to replace the match

mode- Mode of replacement

`Returns:` text_t

`*REGEX_SELECT` (`re` regex)

Selects the text that matches the given regular expression argument. The first match is returned when multiple matches occur in the text. The match may occur anywhere within the text - if you wish to "anchor" this, use "\^" at the start of the regex and/or "$" at the end of the regex. When the regular expression does not match the given string, a Text object of length of 0 is returned.

For example: HTTP.REQ.HEADER("via").REGEX_SELECT(re!NS-CACHE-\\d\\.\\d:\\s*\\d{1,3}!) will select "NS-CACHE-7.0: 70" This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

regex- Regular Expression

`Returns:` text_t

`*REPEAT` (`uint` i)

Produces a string which contains 'i' sequential copies of the input string.

`Parameters``:`

i- the number of times to repeat the string (0 or more)

`Returns:` text_t

`*SET_CHAR_SET` (charset_e charset)

Set the character set to use for subsequent functions that use text.

`Parameters` (expressions not allowed) `:`

charset- Character Set

`Returns:` diameter_flag_t

`*SET_TEXT_MODE` (textmode_e mode)

The mode setting of a Text object controls the behavior of many Text operations. The Text mode settings may also control the behavior of some operations in objects (like List) that build upon the Text object. IGNORECASE, NOIGNORECASE - controls whether string comparison is case sensitive or not. URLENCODED - If set then all Text operations are carried out after translating all %HH or %uHHHH encodings in the underlying byte stream. 1. %HH will be translated to the character Y where HH denotes the ascii value of character Y in hexadecimal. For example, the encoded text "http%3a/.html" will be decoded to "http:/.html" 2. %uWWHH will be translated to the character sequence YZ where WW denotes the ascii value of character Y in hexadecimal and HH denotes the ascii value of character Z in hexadecimal. For example, the encoded text "http%u3a2f.html" and "http%u003a/.html" will both be decoded to"http:/.html" NOURLENCODED - Indicates that no percent encodings are present in the Text object. No percent decoding will be performed on the Text object. PLUS_AS_SPACE - If set then all Text operations are carried out after converting occurrences of the plus character to whitespace. For example, the text "hello+world" will be decoded to "hello world" NO_PLUS_AS_SPACE - If set, then the plus character will not be converted to whitespace in the Text object. BACKSLASH_ENCODED - If set, then all Text operations are carried out after performing the following operations: 1. \\XXX will be translated to the character Y where XXX denotes the ascii value of character Y in octal. The valid range of octal values for this type of encoding is \\0 to \\377. For example, the encoded text "http\\72/.html" and "http\\072/.html" will both be decoded to "http:/.html" 2. \\xHH will be translated to the character Y where HH denotes the ascii value of character Y in hexadecimal. For example, the encoded text "http\\x3a/.html" will be decoded to "http:/.html" 3. \\\\uWWXX will be translated to the character sequence YZ where WW denotes the ascii value of character Y in hexadecimal and XX denotes the ascii value of character Z in hexadecimal. For example, the encoded text "http%u3a2f.html" and "http%u003a/.html" will both be decoded to"http:/.html" 4. Occurences of "\\b", "\\n", "\\t", "\\f" and "\\r" are translated to the corresponding ascii characters. NO_BACKSLASH_ENCODED - If set, then backslash decoding will not be performed on the Text object. BAD_ENCODE_RAISE_UNDEF - If set, then UNDEF is raised if either the URLENCODED or BACKSLASH_ENCODED mode is set and a bad encoding corresponding to the specified encoding mode is encountered. NO_BAD_ENCODE_RAISE_UNDEF - If set, then UNDEF will not be raised when a bad encoding is encountered in the Text object. The Text operations operate on characters (as opposed to operating on bytes). By default a single byte represents a character

using the ASCII encoding. But if URLENCODED mode is set then 3 bytes may represent a character. A PREFIX(3) operation will select the first 3 characters in the Text object. That means it may select up to 9 bytes for URLENCODED Text object. In the case of multibyte decodings as a result of %uXXXX or \\\\uXXXX, Text operations which attempt to treat the multiple decoded bytes as distinct characters are not allowed.

`Parameters` (expressions not allowed) `:`

mode- Text Mode

`Returns:` diameter_flag_t

`*SKIP` (`char` c, `uint` i)

Select the Text after skipping over a prefix of the current Text. The skipped over prefix is the longest prefix that has at most Count (2nd argument) occurrences of character in the 1st argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

c- Character

i- Count

`Returns:` text_t

`*SKIP` (`uint` i)

Select the Text after skipping over a prefix in the current Text. The length of the prefix is equal to the number in the argument. If there aren't enough characters in the Text object then the entire Text is skipped over.

`Parameters` (expressions not allowed) `:`

i- Prefix Length

`Returns:` text_t

`*STARTSWITH_ANY` (text_t patset_name)

Results in Boolean TRUE value if the Text starts with any of the strings that are bound to the patset or dataset named by the string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` bool_at

`*STARTSWITH_INDEX` (text_t patset_name)

Returns the numerical index of the matching string, if the Text starts with any of the strings that are bound to the patset or dataset named by the string argument. Returns 0 if there is no match. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` num_at

`*STARTSWITH` (text_t start)

Results in Boolean TRUE value if a prefix of the Text object matches the string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

start- String

`Returns:` bool_at

`*STRIP_CHARS` (text_t s)

From the selected text remove the characters specified in the string.

For example: Say the selected text is / "foo.xyz=bar" /. Then on executing STRIP_CHARS('.=') or STRIP_CHARS('..=') the selected text will become /fooxyzbar /. Note that repeating character has same effect as it would be if it present only once. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*STRIP_END_CHARS` (text_t s)

Selects the Text after stripping off characters in the end of the current Text object.

For example: Say the selected text is / "foo.xyz=bar" /. Then on executing STRIP_END_CHARS('ar') the selected text will become /foo.xyz=b /. Note that repeating character has same effect as it would be if it present only once. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*STRIP_END_WS`

Selects the Text after stripping off white space in the end of the current Text object.

`Returns:` text_t

`*STRIP_START_CHARS` (text_t s)

Selects the Text after stripping off characters in the beginning of the current Text object.

For example: Say the selected text is / "foo.xyz=bar" /. Then on executing STRIP_START_CHARS('of') the selected text will become /.xyz=bar /. Note that repeating character has same effect as it would be if it present only once. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*STRIP_START_WS`

Selects the Text after stripping off white space in the beginning of the current Text object.

`Returns:` text_t

`*SUBSTR_ANY` (text_t patset_name)

Select any one sub-string that matches any string in the given patset or dataset. The patset cannot have strings longer than 255 characters. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` text_t

`*SUBSTR` (`uint` start, `uint` len)

Select the Text object of the given length at the given offset. Offset it 0 based. If there aren't enough characters after the offset then all the remaining characters are selected.

`Parameters``:`

start- Offset

len- Length

`Returns:` text_t

`*SUBSTR` (text_t s)

Select the first Text object that matches the input string argument. The input string cannot be bigger than 255 characters. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*SUFFIX` (`char` c, `uint` i)

Select a suffix of the Text. The selected suffix is the longest possible suffix containing at most Count (2nd arg) occurrences of the character in the 1st argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

c- Character

i- Count

`Returns:` text_t

`*SUFFIX` (`uint` i)

Select a suffix of the Text. The length of the suffix is equal to the number in the argument. If there aren't enough characters in the Text object then the entire Text is selected.

`Parameters``:`

i- Suffix Length

`Returns:` text_t

`*TO_LOWER`

Converts the selected text to lower case.

For example, the string "ABCd" is converted to "abcd"

`Returns:` text_t

`*TO_UPPER`

Converts the selected text to upper case.

For example, the string "abcD" is converted to "ABCD"

`Returns:` text_t

`*TRUNCATE` (`char` c, `uint` i)

Select the Text after truncating a suffix from the current Text object. The truncated suffix is the longest possible suffix containing at most Count (2nd arg) occurrences of the character in the 1st argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

c- Character

i- Count

`Returns:` text_t

`*TRUNCATE` (`uint` i)

Select the Text after truncating a suffix of the Text. The length of the suffix truncated is equal to the number in the argument. If there aren't enough characters in the Text then then all the characters are truncated.

`Parameters``:`

i- Suffix Length

`Returns:` text_t

`*TYPECAST_AVP_T`

Convert text_t to avp_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (avp_t : Operations that can be performed on the returned AVPs.

`Note:` An AVP can have multiple instances in a Diameter message. However, the system can access only the first 16 instances.

`Example:`

- To get the first value of AVP code 266 from a request, use: DIAMETER.REQ.AVP(266).VALUE(0).
- To get the fourth value of AVP code 266 from a request, use: DIAMETER.REQ.AVP(266).VALUE(3).
- To check if AVP code 1000 in the response has the vendor-specific bit set, use: DIAMETER.RES.AVP(1000).IS_VENDOR_SPECIFIC.

)

`Returns:` avp_t

`*TYPECAST_AVP_UNUM_T`

Convert text_t to avp_unum_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (avp_unum_t : In Diameter AVP based expressions can be written as DIAMETER.REQ.AVP(<avpcode>). For example Auth-Application-Id AVP (AVP code 258) can be extracted as DIAMETER.REQ.AVP(258) For few of the important AVPs we provide aliases. For example this AVP based expression can also be written as DIAMETER.REQ.AUTH_APPLICATION_ID. This expression returns either a object of class avp_t or returns a numerical value (object of class unsigned_long_at). The numerical value for this object is derived from the value in first instance of the AVP.)

`Returns:` avp_unum_t

`*TYPECAST_BOOL_AT`

Convert text_t to bool_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (bool_at : Boolean Operations)

`Returns:` bool_at

`*TYPECAST_COOKIE_T`

Convert text_t to cookie_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (cookie_t : The HTTP Cookie type provides operations for a cookie as it appears in the Set-Cookie and Set-Cookie2 header. In this type the Name-Value List operations are also available. The first delimiter is = and the element delimiter is ;. Multiple consecutive ; are treated as one. (Same as applying the method IGNORE_EMPTY_ELEMENTS on a Name-Value List.) You can use the Name-value List operations to access cookie attributes. The name comparison for all list operations is case insensitive. In this type Text operations are also available. Each cookie begins with a COOKIE_NAME=COOKIE_VALUE pair followed by zero or more semi-colon separated attribute-value pairs. If an attribute appears more than once in a cookie, the value associated with the first appearance of the attribute is returned.

Format Cookie: Cookie1=Value;Version=decimal;Value;Domain=Value;Path=Value)

`Returns:` cookie_t

`*TYPECAST_DIAMETER_FLAG_T`

Convert text_t to diameter_flag_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (diameter_flag_t : Provides operation to treat the underlying 1 byte as set of bit flags. then set/unset/test/reset_all operations can be done on flag)

`Returns:` diameter_flag_t

`*TYPECAST_DNS_DOMAINNAME_T`

Convert text_t to dns_domainname_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (dns_domainname_t : This object provides operations for parsing the DNS domain name as it appears at various places in the DNS data. The format is abc.foo.com.)

`Returns:` dns_domainname_t

`*TYPECAST_DNS_FLAG_T`

Convert text_t to dns_flag_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (dns_flag_t : Provides operations to test/set/unset a flag in dns header.)

`Returns:` dns_flag_t

`*TYPECAST_DOUBLE_AT`

Convert text_t to double_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_at : Double Value)

`Returns:` double_at

`*TYPECAST_DOUBLE_T` (double_format_e format)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error.)

`Parameters` (expressions not allowed) `:`

format- Format

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, double_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, ip_address_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, num_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, time_local_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one

or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, time_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, unsigned_long_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_HTTP_CACHE_CONTROL_T`

Convert text_t to http_cache_control_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_cache_control_t : This object provides for the ability to work on HTTP Cache-Control headers. The name comparison for all list operations is case insensitive.)

`Returns:` http_cache_control_t

`*TYPECAST_HTTP_CONTENT_LENGTH_T`

Convert text_t to http_content_length_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_content_length_t : The HTTP.REQ.CONTENT_LENGTH or HTTP.RES.CONTENT_LENGTH object can be treated as a HTTP Header or as a Number. The numerical value for this object is derived from the value in the last instance of the Content-Length header.)

`Returns:` http_content_length_t

`*TYPECAST_HTTP_COOKIE_T`

Convert text_t to http_cookie_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_cookie_t : This object provides operations for parsing the HTTP cookie header. The name-value pair is derived from the value in the last instance of Cookie header. The format is Cookie : name0=value0; name1=value1; An HTTP Cookie header can have multiple occurrences. COUNT will return a Number containing how many headers of the current type exist. The name comparison for all list operations is case insensitive. The system does not keep track of more than 15 HTTP headers. The result will be undefined if there are more than 15 instances of the header.)

`Returns:` http_cookie_t

`*TYPECAST_HTTP_DATE_T`

Convert text_t to http_date_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_date_t : The HTTP.REQ.DATE or HTTP.RES.DATE object can be treated as a HTTP header or a Time object. The Time value is derived from the value in the last instance of the Date header. The date formats supported are RFC 822 (updated by RFC 1123), RFC 1036 (obsoletes RFC850) and ANSI C asctime() formats.)

`Returns:` http_date_t

`*TYPECAST_HTTP_HEADER_T` (text_t name)

Convert text_t to http_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_header_t : When typecasting a Text object to HTTP Header a header name must be provided.For example: HTTP.REQ.HEADER("MyHdr").TYPECAST_HTTP_HEADER_T("InHdr"))

`Parameters` (expressions not allowed) `:`

name- Header Name

`Returns:` http_header_t

`*TYPECAST_HTTP_HOSTNAME_T`

Convert text_t to http_hostname_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_hostname_t : This object provides operations for parsing the HTTP hostname as it appears at various places in the HTTP protocol data. The format is abc.foo.com:8080.)

`Returns:` http_hostname_t

`*TYPECAST_HTTP_METHOD_T`

Convert text_t to http_method_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_method_t : This object provides Text operations and HTTP Request Method Enum operations on the HTTP request method.)

`Returns:` http_method_t

`*TYPECAST_HTTP_SET_COOKIE_T`

Convert text_t to http_set_cookie_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_set_cookie_t : HTTP.RES.SET_COOKIE provides operations for parsing and operating on the SET-COOKIE header that is present in the HTTP response. HTTP Set-Cookie header supports Text and HTTP Header operations. For most Text operations the value in the last Set-Cookie header is selected. HTTP Set-Cookie header also supports special operations to extract cookies from the response. It is assumed that there will be only one cookie in a Set-Cookie header.)

`Returns:` http_set_cookie_t

`*TYPECAST_HTTP_URL_T`

Convert text_t to http_url_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_url_t : HTTP.REQ.URL provides operations for parsing and operating on the URL that is present in the first line of the HTTP request header. The supported format is \[<protocol>://<hostname>\]<path>?<query>. The Text object backing a HTTP URL object has the Text Mode set to URLENCODED by default.)

`Returns:` http_url_t

`*TYPECAST_HTTP_VERSION_T`

Convert text_t to http_version_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_version_t : HTTP.REQ.VERSION or HTTP.RES.VERSION provide operations to extract HTTP version information.)

`Returns:` http_version_t

`*TYPECAST_IPV6_ADDRESS_AT`

Convert text_t to ipv6_address_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ipv6_address_at : Provides operations for the 128-bit IPv6 address value. Some general information regarding IPv6 expressions: IPv6 PIXL expressions can be combined with other PIXL expressions using the '+' operator. The output is expected to be the concatenation of the string representations of the individual PIXL expressions. No other operator other than '+' is expected to work when any of the operands is an IPv6 PIXL expression. Also, IPv6 PIXL expressions can be combined with any other type of PIXL expression except a PIXL expression that produces a bool result. In other words, if A and/or B are two IPv6 addresses, A+B should result in the string AB. When one of A or B is an IPv6 address, the other can only be a number or a string and not a boolean. Further, when A and/or B is an IPv6 address, the only operator allowed between them is '+'.

Example: Let the client source IPv6 address be ABCD:1234::ABCD. Let the server destination IPv4 address be 10.100.10.100. Then the expression CLIENT.IPV6.SRC + SERVER.IP.DST should produce the output "ABCD:1234::ABCD10.100.10.100". Similarly, CLIENT.IPV6.SRC + 5 should produce the result ABCD:1234::ABCD5)

`Returns:` ipv6_address_at

`*TYPECAST_IPV6_ADDRESS_T`

Convert text_t to ipv6_address_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ipv6_address_t : This object represents an IPv6 address present in the 1000:1001:CD10:0000:0000:89AB:4567:CDEF format.)

`Returns:` ipv6_address_t

`*TYPECAST_IPV6_SUBNET_AT`

Convert text_t to ipv6_subnet_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ipv6_subnet_at : Provides operations for the integral IPv6 subnet address value.)

`Returns:` ipv6_subnet_at

`*TYPECAST_IPV6_SUBNET_T`

Convert text_t to ipv6_subnet_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ipv6_subnet_t : This object represents an IPv6 subnet address present in the 1000:1001:CD10:0000:0000:89AB:4567:CDEF/64 format.)

`Returns:` ipv6_subnet_t

`*TYPECAST_IP_ADDRESS_AT`

Convert text_t to ip_address_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ip_address_at : Provides operations for the 32-bit integral IP address value.)

`Returns:` ip_address_at

`*TYPECAST_IP_ADDRESS_T`

Convert text_t to ip_address_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ip_address_t : Represents an IP address present in the 10.100.200.1 format.)

`Returns:` ip_address_t

`*TYPECAST_IP_OPTIONS_T`

Convert text_t to ip_options_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ip_options_t : IP protocol options)

`Returns:` ip_options_t

`*TYPECAST_IP_OPTIONS_TYPE_T`

Convert text_t to ip_options_type_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ip_options_type_t : IP Options Type)

`Returns:` ip_options_type_t

`*TYPECAST_IP_TOS_T`

Convert text_t to ip_tos_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ip_tos_t : Provides operations to TOS field in IP header.)

`Returns:` ip_tos_t

`*TYPECAST_LIST_T` (`char` sep)

Convert text_t to list_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (list_t : The character separator has to be provided when typecasting a textual context to list type. The current text mode has no effect on the character separator. For example if the current text mode is IGNORECASE and the separator is p then P will not be treated as a separator.)

`Parameters` (expressions not allowed) `:`

sep- Separator

`Returns:` list_t

`*TYPECAST_MAC_ADDRESS_AT`

Convert text_t to mac_address_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (mac_address_at : Provides operations for the 48-bit MAC address value.)

`Returns:` mac_address_at

`*TYPECAST_MAC_ADDRESS_T`

Convert text_t to mac_address_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (mac_address_t : Represents a MAC address present in the 12:34:56:78:9a:bc format.)

`Returns:` mac_address_t

`*TYPECAST_NUM_AT`

Convert text_t to num_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (num_at : Number Value)

`Returns:` num_at

`*TYPECAST_NUM_T` (num_format_e format)

Convert text_t to num_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (num_t : Treat the underlying text as a Number in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error.)

`Parameters` (expressions not allowed) `:`

format- Format

`Returns:` num_t

`*TYPECAST_NUM_T` (num_format_e format, num_at default_value)

Convert text_t to num_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (num_t : Treat the underlying text as a Number in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` num_t

`*TYPECAST_NVLIST_T` (`char` sep1, `char` sep2)

Convert text_t to nvlist_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (nvlist_t : Two character delimiters have to be provided when typecasting a Text object to a Name-Value List. The first delimited separates the name from the value. The second delimiter separates list items. For example typecast_nvlist_t('=', '&') handles a URL query string. The Text Mode has no effect on the character delimiters. For example if the current text mode is IGNORECASE and a delimiter is p then P will not be treated as a delimiter.)

`Parameters` (expressions not allowed) `:`

sep1- delimiter1

sep2- delimiter2

`Returns:` nvlist_t

`*TYPECAST_NVLIST_T` (`char` sep1, `char` sep2, `char` quote)

Convert text_t to nvlist_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (nvlist_t : Two character delimiters and quote-character have to be provided when typecasting a Text object to a Name-Value List that supports quote-character. The first delimited separates the name from the value. The second delimiter separates list items. The third value specifies the quote character. For example typecast_nvlist_t('=', ';', "") handles a name-value list separated by semi-colons that allows quoting. The quote-character specifies that the value can occur within the quotes and the delimiters within the quote-characters should not be taken into account. The Text Mode has no effect on the character delimiters. For example if the current text mode is IGNORECASE and a delimiter is p then P will not be treated as a delimiter.)

`Parameters` (expressions not allowed) `:`

sep1- delimiter1

sep2- delimiter2

quote- quote-character.

`Returns:` nvlist_t

`*TYPECAST_PROTOCOL_BUFFER_T`

Convert text_t to protocol_buffer_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (protocol_buffer_t : gRPC Protocol Buffers interface)

`Returns:` protocol_buffer_t

`*TYPECAST_RADIUS_AVP_T`

Convert text_t to radius_avp_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (radius_avp_t : Operations that can be performed on the returned AVPs.

`Note:` An AVP can have multiple instances in a radius message. However, the system can access only the first 16 instances.

`Example:`

- To get the first value of AVP code 26 from a request, use: radius.REQ.AVP(26).VALUE(0).
- To get the fourth value of AVP code 26 from a request, use: radius.REQ.AVP(26).VALUE(3).

)

`Returns:` radius_avp_t

`*TYPECAST_RADIUS_AVP_VALUE_T`

Convert text_t to radius_avp_value_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (radius_avp_value_t : Provides operations to typecast RADIUS AVP value to Integer value or IP Address.)

`Returns:` radius_avp_value_t

`*TYPECAST_SEQ_TEXT_T`

Convert text_t to seq_text_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (seq_text_t : Represents the Text Sequence class.)

`Returns:` seq_text_t

`*TYPECAST_SERVICEPATH_T`

Convert text_t to servicepath_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (servicepath_t : Operations that can be performed on the service path.

`Example:`

- To get the name of the service path applicable to current subscriber, use: SUBSCRIBER.SERVICEPATH

- To determine If the service function is the next in the service path applicable to scubscriber, use: SUBSCRIBER.SERVICEPATH.IS_NEXT().

)

`Returns:` servicepath_t

`*TYPECAST_SIP_CALLID_HEADER_T`

Convert text_t to sip_callid_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_callid_header_t : This object provides operations for parsing the SIP callid header.)

`Returns:` sip_callid_header_t

`*TYPECAST_SIP_CONTENT_LENGTH_T`

Convert text_t to sip_content_length_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_content_length_t : The SIP.REQ.CONTENT_LENGTH or SIP.RES.CONTENT_LENGTH object can be treated as a SIP Header or as a Number. The numerical value for this object is derived from the value in the last instance of the Content-Length header.)

`Returns:` sip_content_length_t

`*TYPECAST_SIP_FROM_HEADER_T`

Convert text_t to sip_from_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_from_header_t : This object provides operations for parsing the SIP From header.)

`Returns:` sip_from_header_t

`*TYPECAST_SIP_HEADER_T` (text_t name)

Convert text_t to sip_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_header_t : When typecasting a Text object to SIP Header a header name must be provided.For example: SIP.REQ.HEADER("MyHdr").TYPECAST_SIP_HEADER_T("InHdr"))

`Parameters` (expressions not allowed) `:`

name- Header Name

`Returns:` sip_header_t

`*TYPECAST_SIP_HOSTNAME_T`

Convert text_t to sip_hostname_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_hostname_t : This object provides operations for parsing the SIP hostname as it appears at various places in the SIP protocol data. The format is abc.foo.com:5060.)

`Returns:` sip_hostname_t

`*TYPECAST_SIP_METHOD_T`

Convert text_t to sip_method_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_method_t : This object provides Text operations and SIP Request Method Enum operations on the SIP request method.)

`Returns:` sip_method_t

`*TYPECAST_SIP_TO_HEADER_T`

Convert text_t to sip_to_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_to_header_t : This object provides operations for parsing the SIP From header.)

`Returns:` sip_to_header_t

`*TYPECAST_SIP_URL_T`

Convert text_t to sip_url_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_url_t : SIP.REQ.URL provides operations for parsing and operating on the URL that is present in the first line of the SIP request header. The supported format is \[<protocol>://<hostname>\]<path>?<query>. The Text object backing a SIP URL object has the Text Mode set to URLENCODED by default.)

`Returns:` sip_url_t

`*TYPECAST_SIP_VERSION_T`

Convert text_t to sip_version_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_version_t : SIP.REQ.VERSION or SIP.RES.VERSION provide operations to extract SIP version information.)

`Returns:` sip_version_t

`*TYPECAST_SIP_VIA_HEADER_T`

Convert text_t to sip_via_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_via_header_t : This object provides operations for parsing the SIP Via header.)

`Returns:` sip_via_header_t

`*TYPECAST_SSLVPN_MODE_T`

Convert text_t to sslvpn_mode_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sslvpn_mode_t : This object provides Text operations and SSLVPN Mode Enum operations on the SSLVPN request method.)

`Returns:` sslvpn_mode_t

`*TYPECAST_SSL_TEXT_T` (text_t name)

Convert text_t to ssl_text_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ssl_text_t : Treat the underlying text object as SSL Text.)

`Parameters` (expressions not allowed) `:`

name- Name

`Returns:` ssl_text_t

`*TYPECAST_TCP_OPTIONS_T`

Convert text_t to tcp_options_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (tcp_options_t : TCP Protocol Options)

`Returns:` tcp_options_t

`*TYPECAST_TCP_OPTIONS_TYPE_T`

Convert text_t to tcp_options_type_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (tcp_options_type_t : TCP Protocol Options Type)

`Returns:` tcp_options_type_t

`*TYPECAST_TCP_REPEATER_OPTION_T`

Convert text_t to tcp_repeater_option_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (tcp_repeater_option_t : TCP Protocol Option : Repeater)

`Returns:` tcp_repeater_option_t

`*TYPECAST_TIME_AT`

Convert text_t to time_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (time_at : Treats a number value as number of seconds since GMT Jan 1 1970 0h 0m 0s.)

`Returns:` time_at

`*TYPECAST_TIME_LOCAL_AT`

Convert text_t to time_local_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (time_local_at : Treats a number value as number of seconds since GMT Jan 1 1970 0h 0m 0s as adjsuted for the local time zone.)

`Returns:` time_local_at

`*TYPECAST_TIME_T`

Convert text_t to time_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (time_t : This object treats a Text object as a date string. The formats supported are

1\. RFC822 :: Sun, 06 Nov 1994 08:49:37 GMT 2\. RFC850 :: Sunday, 06-Nov-94 08:49:37 GMT 3\. ASCTIME :: Sun Nov 6 08:49:37 1994 4\. ASCTIME like :: Sun Nov 6 08:49:37 1994 5\. ASCTIME like :: Sun Nov 06 08:49:37 1994 6\. Http Set-Cookie Expiry date :: Sun, 06-Nov-1994 08:49:37 GMT)

`Returns:` time_t

`*TYPECAST_UNSIGNED_LONG_AT`

Convert text_t to unsigned_long_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_at : Unsigned Long(64bit) Value)

`Returns:` unsigned_long_at

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error.)

`Parameters` (expressions not allowed) `:`

format- Format

`Returns:` unsigned_long_t

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format, ip_address_at default_value)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` unsigned_long_t

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format, unsigned_long_at default_value)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining

characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` unsigned_long_t

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format, num_at default_value)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` unsigned_long_t

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format, time_local_at default_value)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` unsigned_long_t

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format, time_at default_value)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` unsigned_long_t

`*TYPECAST_UNUM_TEXT_T`

Convert text_t to unum_text_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unum_text_t : Provides operations to treat the underlying OctectString as Binary String or unsigned long value .)

`Returns:` unum_text_t

`*TYPECAST_URL_CATEGORY_T`

Convert text_t to url_category_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (url_category_t : Retrieves URL category and attributes from an URL)

`Returns:` url_category_t

`*TYPECAST_VENDOR_SPEC_APPID_AVP_T`

Convert text_t to vendor_spec_appid_avp_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (vendor_spec_appid_avp_t : Retrieves AVPs that are nested in the grouped AVP Vendor-Specific-Application-Id (code 260). The nested AVPs are:

- Vendor-Id
- Auth-Application-Id
- Acct-Application-Id

For example, to retrieve the Auth-Application-Id AVP from the Vendor-Specific-Application-Id AVP:

- For requests:
  DIAMETER.REQ.VENDOR_SPECIFIC_APPLICATION_ID.AUTH_APPLICATION_ID
- For responses:
  DIAMETER.RES.VENDOR_SPECIFIC_APPLICATION_ID.AUTH_APPLICATION_ID

)

`Returns:` vendor_spec_appid_avp_t

`*TYPECAST_VENDOR_SPEC_RADIUS_AVP_T`

Convert text_t to vendor_spec_radius_avp_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (vendor_spec_radius_avp_t :

- Vendor-Id

To retrieve the Vendor-Id from the Vendor-Specific AVP:

- RADIUS.REQ.VENDOR_SPECIFIC.VENDORID

)

`Returns:` vendor_spec_radius_avp_t

`*UNQUOTE` (`char` c)

If selected text is quoted by character c, Remove character c from beginning and end.

For example: Say the selected text is / "foo xyz bar " /. Then on executing UNQUOTE("") the selected text will become /foo xyz bar / This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

c- Character

`Returns:` text_t

`*URLSET_MATCHES_ANY` (text_t urlset_name)

Results in Boolean TRUE value if and only if the Text matches any of the patterns that are specified in the urlset named by the string argument. The matching is case-insensitive for domains, but case-sensitive for paths. For example:

- HTTP.REQ.HOST.APPEND(HTTP.REQ.URL).URLSET_MATCHES_ANY("urlset_forbidden") returns true when the combined domain and URL matches any pattern in the urlset whose name is "urlset_forbidden".

`Parameters` (expressions not allowed) `:`

urlset_name- urlset name

`Returns:` bool_at

`*URL_CATEGORIZE` (`uint` min_reputation, `uint` max_reputation)

Returns the URL category for the supplied URL with the given minimum and maximum reputation score. Where a score of 5 is most risky and 1 is least risky. If either score is set to 0, that bound would be ignored. By specifying the reputation scores, the function will returned the category with the highest score (most risky) based on the bounds. If there was an error getting the category or if the URL is invalid then it will result in an Undef error. For example: HTTP.REQ.HOST.APPEND(HTTP.REQ.URL).URL_CATEGORIZE(0, 0) returns value when the combined domain and URL is looked up for the URL category with the highest reputation score (most risky).

`Parameters` (expressions not allowed) `:`

min_reputation- Minimum reputation score of URL category

max_reputation- Maximum reputation score of URL category

`Returns:` url_category_t

`*URL_RESERVED_CHARS_SAFE`

Converts URL reserved characters to corresponding '%XX' values and retains the rest. This is a read only operation.

```
Based on RFC3986, following are considered URL unreserved characters:

    Alpha-numeric characters: a-z, A-Z, 0-9

    Hyphen and underscore: "-", "_"

    Dot: "."

    Tilde: "~"
```

The rest are converted to %XX encoding, 'XX' is the hex-based representation of the input character. If the requirement is to encode all but URL safe characters, please consider using HTTP_URL_SAFE method.

`Returns:` text_t

`*XML_DECRYPT` (text_t certKeyName)

Decrypt the selected content, which was encrypted using the W3C XML Encryption standard.

`Parameters` (expressions not allowed) `:`

certKeyName- identifies the certkey object containing the RSA private key to be used to decrypt the bulk encryption key in the selected EncryptedData element.

`Returns:` text_t

`*XML_ENCRYPT` (text_t certKeyName, encrypt_method_e method)

Encrypt the selected cleartext using the W3C XML Encryption standard.

`Parameters` (expressions not allowed) `:`

certKeyName- identifies the certkey object containing an X.509 certificate with the RSA public key to be used to encrypt the generated bulk encryption key. Note that the certKey object need not, and usually will not, include the associated RSA private key.

method- specifies the bulk encryption method (rc4, des3, aes128, aes192, or aes256) used to encrypt the content.

`Returns:` text_t

`*XML_ENCRYPT` (text_t certKeyName, encrypt_method_e method, `uint` flags)

Encrypt the selected cleartext using the W3C XML Encryption standard.

`Parameters` (expressions not allowed) `:`

certKeyName- identifies the certkey object containing an X.509 certificate with the RSA public key to be used to encrypt the generated bulk encryption key. Note that the certKey object need not, and usually will not, include the associated RSA private key.

method- specifies the bulk encryption method (rc4, des3, aes128, aes192, or aes256) used to encrypt the content.

flags- optional bit mask to specify optional elements in the EncryptedData element. These are hints to tell the receiver what private key to use to decrypt the bulk encryption key, providing information from the certKey's X.509 certificate.

- 1 - include a KeyName element with the certKeyName;
- 2 - include a KeyValue element with the RSA public key from the certificate;
- 4 - include an X509IssuerSerial element with the certificate serial number and issuer DN;
- 8 - include an X509SubjectName element with the certificate subject DN;
- 16 - include an X509Certificate element with the entire certificate;

`Returns:` text_t

`*XPATH_HTML_WITH_MARKUP` (`xpath_str` xpathex)

Applies an XPath expression to the DOM for an HTML document and returns the selected node-set or string, including markup like element tags. node-sets are converted to strings using the standard XPath string conversion routine. The selected portion of the document can be used as the target for rewrite actions.

Examples: HTTP.REQ.BODY(1000).XPATH_HTML_WITH_MARKUP(xp%//md/head/title%) returns the <title> element in the document's <head> This can be used in a rewrite action to replace or delete the <title> element.

`Parameters` (expressions not allowed) `:`

xpathex- XPath Expression

`Returns:` text_t

`*XPATH_HTML` (`xpath_bool` xpathex)

Applies an XPath expression to the DOM for an HTML document and a boolean value.

Examples: HTTP.RES.BODY(1000).XPATH_HTML(xp%boolean(/md/head/meta)%) returns true if the <meta> element exists as a child of <head> element.

`Parameters` (expressions not allowed) `:`

xpathex- XPath Expression

`Returns:` bool_at

`*XPATH_HTML` (`xpath_double` xpathex)

Applies an XPath expression to the DOM for an HTML document and a double value.

Examples: HTTP.RES.BODY(1000).XPATH_HTML(xp%number(//video/@height)%) returns the numeric value of the height attribute of the first <video> element.

`Parameters` (expressions not allowed) `:`

xpathex- XPath Expression

`Returns:` double_at

`*XPATH_HTML` (`xpath_str` xpathex)

Applies an XPath expression to the DOM for an HTML document and returns the selected node-set or string. node-sets are converted to strings using the standard XPath string conversion routine.

Examples: HTTP.REQ.BODY(1000).XPATH_HTML(xp%//img/@src%) returns the string value of the src attribute of the first

DIAMETER_MESSAGE_T

Define common operations for Diameter.Req or Diameter.Res.

This topic lists the expressions that are provided by this class.

- `ACCOUNTING_SUB_SESSION_ID`

  Returns the Accounting-Sub-Session-Id AVP (code 287) from the message.

`Returns:` avp_t

- `ACCT_APPLICATION_ID`

  Returns the Acct-Application-Id AVP (code 259) from the message. `Note:` expression can be used to retrieve the value as Unsigned32

`Returns:` avp_unum_t

- `ACCT_MULTI_SESSION_ID`

  Returns the Acct-Multi-Session-Id AVP (code 50) from the message.

`Returns:` avp_t

- `ACCT_SESSION_ID`

  Returns the Acct-Session-ID AVP (code 44) from the message.

`Returns:` avp_t

- `APPLICATION_ID`

  Returns the Application-ID from the message.

`Returns:` unum_text_t

- `AUTH_APPLICATION_ID`

  Returns the Auth-Application-Id AVP (code 258) from the message. `Note:` expression can be used to retrieve the value as Unsigned32

`Returns:` avp_unum_t

- `AVP_END`

  Returns the location at the end of Diameter message (or in other words end of all AVPs) in Diameter message.

`Returns:` text_t

- `AVP_LIST`

  Returns the AVP region in Diameter message (or in other words returns location at start of AVPs and length equal to Diameter message length excluding header).

`Returns:` text_t

`AVP` (`uint` avpcode)

Returns the specified AVP from the message.

For example, to get the AVP with code 263 from a Request, use the expression: DIAMETER.REQ.AVP(263).

`Note:` To get AVP that is nested inside a grouped AVP, use the AVP method from the avp_t class.

`Parameters` (expressions not allowed) `:`

avpcode- AVP code

`Returns:` avp_t

`AVP` (`uint` avpcode, `uint` vendorid)

Returns the specified AVP in given vendor-id namespace from the message.

For example, to get the AVP with code 1001 and VendorId 10415 from a Request, use the expression: DIAMETER.REQ.AVP(1001, 10415).

`Note:` To get AVP that is nested inside a grouped AVP, use the AVP method from the avp_t class.

`Parameters` (expressions not allowed) `:`

avpcode- AVP code

vendorid- Vendor Id

`Returns:` avp_t

- `AVP_START`

  Returns the location at the start of AVPs (or in other words end of diameter header) in Diameter message.

`Returns:` text_t

- `COMMAND_CODE`

  Returns the Command Code from the message.

`Returns:` unum_text_t

- `END_TO_END_ID`

  Returns the End-to-End Identifier from the message.

`Returns:` unsigned_long_at

- `FLAGS`

  Returns the value of Diameter Header flags in Diameter message.

`Returns:` diameter_flag_t

- `HOP_BY_HOP_ID`

  Returns the Hop-by-Hop Identifier from the message.

`Returns:` unsigned_long_at

- `IS_PROXIABLE`

  Returns true if the P (proxiable) command flag is set for the message.

`Returns:` bool_at

- `LENGTH`

  Returns the Message Length from the message.

`Returns:` num_at

- `ORIGIN_HOST`

Returns the Origin-Host AVP (code 264) from the message.

`Returns:` avp_t

- `ORIGIN_REALM`

  Returns the Origin-Realm AVP (code 296) from the message.

`Returns:` avp_t

- `PRODUCT_NAME`

  Returns the Product-Name AVP (code 269) from the message.

`Returns:` avp_t

- `SESSION_ID`

  Returns the Session-ID AVP (code 263) from the message.

`Returns:` avp_t

- `SUPPORTED_VENDOR_ID`

  Returns the Supported-Vendor-Id AVP (code 265) from the message.

`Returns:` avp_t

- `USER_NAME`

  Returns the User-Name AVP (code 1) from the message.

`Returns:` avp_t

- `VENDOR_ID`

  Returns the Vendor-Id AVP (code 266) from the message.

`Returns:` avp_t

- `VENDOR_SPECIFIC_APPLICATION_ID`

  Returns the Vendor-Specific-Application-Id AVP (code 260) from the message.

`Returns:` vendor_spec_appid_avp_t

- `VERSION`

Returns the version of the Diameter protocol. Currently, Diameter supports only version 1.

`Returns:` unum_text_t

DIAMETER_PROTOCOL_T

Provides expressions to retrieve Diameter header information and Diameter Header and AVPs (attribute value pairs) from Diameter requests and responses.

`Note:` The Diameter implementation is RFC 6733 compliant.

This topic lists the expressions that are provided by this class.

- `IS_CLIENT`

  Returns true if this is a Diameter client connection.

`Returns:` bool_at

- `IS_SERVER`

  Returns true if this is a Diameter server connection.

`Returns:` bool_at

- `NEW_ANSWER`

  Creates new Diameter Response Message (Header only) based on Request header.

`Returns:` text_t

`NEW_ANSWER` (bool_at error, ip_address_at command_code, ip_address_at application_id)

Creates new Diameter Message (Header only) based on given parameters.

`Parameters``:`

error- Error flag

command_code- Command associated with the Diameter message

application_id- Application id to be used in Diameter Header

`Returns:` text_t

`NEW_ANSWER` (bool_at error, ip_address_at command_code, num_at application_id)

Creates new Diameter Message (Header only) based on given parameters.

`Parameters``:`

error- Error flag

command_code- Command associated with the Diameter message

application_id- Application id to be used in Diameter Header

`Returns:` text_t

`NEW_ANSWER` (bool_at error, ip_address_at command_code, time_local_at application_id)

Creates new Diameter Message (Header only) based on given parameters.

`Parameters``:`

error- Error flag

command_code- Command associated with the Diameter message

application_id- Application id to be used in Diameter Header

`Returns:` text_t

`NEW_ANSWER` (bool_at error, ip_address_at command_code, time_at application_id)

Creates new Diameter Message (Header only) based on given parameters.

`Parameters``:`

error- Error flag

command_code- Command associated with the Diameter message

application_id- Application id to be used in Diameter Header

`Returns:` text_t

`NEW_ANSWER` (bool_at error, ip_address_at command_code, unsigned_long_at application_id)

Creates new Diameter Message (Header only) based on given parameters.

`Parameters``:`

error- Error flag

command_code- Command associated with the Diameter message

application_id- Application id to be used in Diameter Header

`Returns:` text_t

`NEW_ANSWER` (bool_at error, num_at command_code, ip_address_at application_id)

Creates new Diameter Message (Header only) based on given parameters.

`Parameters``:`

error- Error flag

command_code- Command associated with the Diameter message

application_id- Application id to be used in Diameter Header

`Returns:` text_t

`NEW_ANSWER` (bool_at error, num_at command_code, num_at application_id)

Creates new Diameter Message (Header only) based on given parameters.

`Parameters``:`

error- Error flag

command_code- Command associated with the Diameter message

application_id- Application id to be used in Diameter Header

`Returns:` text_t

`NEW_ANSWER` (bool_at error, num_at command_code, time_local_at application_id)

Creates new Diameter Message (Header only) based on given parameters.

`Parameters``:`

error- Error flag

command_code- Command associated with the Diameter message

application_id- Application id to be used in Diameter Header

`Returns:` text_t

`NEW_ANSWER` (bool_at error, num_at command_code, time_at application_id)

Creates new Diameter Message (Header only) based on given parameters.

`Parameters``:`

error- Error flag

command_code- Command associated with the Diameter message

application_id- Application id to be used in Diameter Header

`Returns:` text_t

`NEW_ANSWER` (bool_at error, num_at command_code, unsigned_long_at application_id)

Creates new Diameter Message (Header only) based on given parameters.

`Parameters``:`

error- Error flag

command_code- Command associated with the Diameter message

application_id- Application id to be used in Diameter Header

`Returns:` text_t

`NEW_ANSWER` (bool_at error, time_local_at command_code, ip_address_at application_id)

Creates new Diameter Message (Header only) based on given parameters.

`Parameters``:`

error- Error flag

command_code- Command associated with the Diameter message

application_id- Application id to be used in Diameter Header

`Returns:` text_t

`NEW_ANSWER` (bool_at error, time_local_at command_code, num_at application_id)

Creates new Diameter Message (Header only) based on given parameters.

`Parameters``:`

error- Error flag

command_code- Command associated with the Diameter message

application_id- Application id to be used in Diameter Header

`Returns:` text_t

`NEW_ANSWER` (bool_at error, time_local_at command_code, time_local_at application_id)

Creates new Diameter Message (Header only) based on given parameters.

`Parameters``:`

error- Error flag

command_code- Command associated with the Diameter message

application_id- Application id to be used in Diameter Header

`Returns:` text_t

`NEW_ANSWER` (bool_at error, time_local_at command_code, time_at application_id)

Creates new Diameter Message (Header only) based on given parameters.

`Parameters``:`

error- Error flag

command_code- Command associated with the Diameter message

application_id- Application id to be used in Diameter Header

`Returns:` text_t

`NEW_ANSWER` (bool_at error, time_local_at command_code, unsigned_long_at application_id)

Creates new Diameter Message (Header only) based on given parameters.

`Parameters``:`

error- Error flag

command_code- Command associated with the Diameter message

application_id- Application id to be used in Diameter Header

`Returns:` text_t

`NEW_ANSWER` (bool_at error, time_at command_code, ip_address_at application_id)

Creates new Diameter Message (Header only) based on given parameters.

`Parameters``:`

error- Error flag

command_code- Command associated with the Diameter message

application_id- Application id to be used in Diameter Header

`Returns:` text_t

`NEW_ANSWER` (bool_at error, time_at command_code, num_at application_id)

Creates new Diameter Message (Header only) based on given parameters.

`Parameters``:`

error- Error flag

command_code- Command associated with the Diameter message

application_id- Application id to be used in Diameter Header

`Returns:` text_t

`NEW_ANSWER` (bool_at error, time_at command_code, time_local_at application_id)

Creates new Diameter Message (Header only) based on given parameters.

`Parameters``:`

error- Error flag

command_code- Command associated with the Diameter message

application_id- Application id to be used in Diameter Header

`Returns:` text_t

`NEW_ANSWER` (bool_at error, time_at command_code, time_at application_id)

Creates new Diameter Message (Header only) based on given parameters.

`Parameters``:`

error- Error flag

command_code- Command associated with the Diameter message

application_id- Application id to be used in Diameter Header

`Returns:` text_t

`NEW_ANSWER` (bool_at error, time_at command_code, unsigned_long_at application_id)

Creates new Diameter Message (Header only) based on given parameters.

`Parameters``:`

error- Error flag

command_code- Command associated with the Diameter message

application_id- Application id to be used in Diameter Header

`Returns:` text_t

`NEW_ANSWER` (bool_at error, unsigned_long_at command_code, ip_address_at application_id)

Creates new Diameter Message (Header only) based on given parameters.

`Parameters``:`

error- Error flag

command_code- Command associated with the Diameter message

application_id- Application id to be used in Diameter Header

`Returns:` text_t

`NEW_ANSWER` (bool_at error, unsigned_long_at command_code, num_at application_id)

Creates new Diameter Message (Header only) based on given parameters.

`Parameters``:`

error- Error flag

command_code- Command associated with the Diameter message

application_id- Application id to be used in Diameter Header

`Returns:` text_t

`NEW_ANSWER` (bool_at error, unsigned_long_at command_code, time_local_at application_id)

Creates new Diameter Message (Header only) based on given parameters.

`Parameters``:`

error- Error flag

command_code- Command associated with the Diameter message

application_id- Application id to be used in Diameter Header

`Returns:` text_t

`NEW_ANSWER` (bool_at error, unsigned_long_at command_code, time_at application_id)

Creates new Diameter Message (Header only) based on given parameters.

`Parameters``:`

error- Error flag

command_code- Command associated with the Diameter message

application_id- Application id to be used in Diameter Header

`Returns:` text_t

`NEW_ANSWER` (bool_at error, unsigned_long_at command_code, unsigned_long_at application_id)

Creates new Diameter Message (Header only) based on given parameters.

`Parameters``:`

error- Error flag

command_code- Command associated with the Diameter message

application_id- Application id to be used in Diameter Header

`Returns:` text_t

`NEW_AVP_FLOAT32` (`uint` avpcode, double_at avpvalue)

Creates new AVP based on given avp code and given Float32 value. Vendor-Specific and Mandatory bit are not set.

`Parameters``:`

avpcode- AVP code

avpvalue- AVP value

`Returns:` text_t

`NEW_AVP_FLOAT32` (`uint` avpcode, ip_address_at avpvalue)

Creates new AVP based on given avp code and given Float32 value. Vendor-Specific and Mandatory bit are not set.

`Parameters``:`

avpcode- AVP code

avpvalue- AVP value

`Returns:` text_t

`NEW_AVP_FLOAT32` (`uint` avpcode, num_at avpvalue)

Creates new AVP based on given avp code and given Float32 value. Vendor-Specific and Mandatory bit are not set.

`Parameters``:`

avpcode- AVP code

avpvalue- AVP value

`Returns:` text_t

`NEW_AVP_FLOAT32` (`uint` avpcode, time_local_at avpvalue)

Creates new AVP based on given avp code and given Float32 value. Vendor-Specific and Mandatory bit are not set.

`Parameters``:`

avpcode- AVP code

avpvalue- AVP value

`Returns:` text_t

`NEW_AVP_FLOAT32` (`uint` avpcode, time_at avpvalue)

Creates new AVP based on given avp code and given Float32 value. Vendor-Specific and Mandatory bit are not set.

`Parameters``:`

avpcode- AVP code

avpvalue- AVP value

`Returns:` text_t

`NEW_AVP_FLOAT32` (`uint` avpcode, unsigned_long_at avpvalue)

Creates new AVP based on given avp code and given Float32 value. Vendor-Specific and Mandatory bit are not set.

`Parameters``:`

avpcode- AVP code

avpvalue- AVP value

`Returns:` text_t

`NEW_AVP_FLOAT32` (`uint` avpcode, double_at avpvalue, bool_at is_mandatory, `uint` vendor_id)

Creates new AVP based on given avp code and given Float32 value. Set the 'M' and 'V' bits, and vendor_id field for this AVP.

`Parameters``:`

avpcode- AVP code

avpvalue- AVP value

is_mandatory- 'true' to set The 'M' bit in AVP

vendor_id- vendor_id field. non-zero vendor_id sets the 'V' bit and fills the vendor_id field in AVP as given.

`Returns:` text_t

`NEW_AVP_FLOAT32` (`uint` avpcode, ip_address_at avpvalue, bool_at is_mandatory, `uint` vendor_id)

Creates new AVP based on given avp code and given Float32 value. Set the 'M' and 'V' bits, and vendor_id field for this AVP.

`Parameters``:`

avpcode- AVP code

avpvalue- AVP value

is_mandatory- 'true' to set The 'M' bit in AVP

vendor_id- vendor_id field. non-zero vendor_id sets the 'V' bit and fills the vendor_id field in AVP as given.

`Returns:` text_t

`NEW_AVP_FLOAT32` (`uint` avpcode, num_at avpvalue, bool_at is_mandatory, `uint` vendor_id)

Creates new AVP based on given avp code and given Float32 value. Set the 'M' and 'V' bits, and vendor_id field for this AVP.

`Parameters``:`

avpcode- AVP code

avpvalue- AVP value

is_mandatory- 'true' to set The 'M' bit in AVP

vendor_id- vendor_id field. non-zero vendor_id sets the 'V' bit and fills the vendor_id field in AVP as given.

`Returns:` text_t

`NEW_AVP_FLOAT32` (`uint` avpcode, time_local_at avpvalue, bool_at is_mandatory, `uint` vendor_id)

Creates new AVP based on given avp code and given Float32 value. Set the 'M' and 'V' bits, and vendor_id field for this AVP.

`Parameters``:`

avpcode- AVP code

avpvalue- AVP value

is_mandatory- 'true' to set The 'M' bit in AVP

vendor_id- vendor_id field. non-zero vendor_id sets the 'V' bit and fills the vendor_id field in AVP as given.

`Returns:` text_t

`NEW_AVP_FLOAT32` (`uint` avpcode, time_at avpvalue, bool_at is_mandatory, `uint` vendor_id)

Creates new AVP based on given avp code and given Float32 value. Set the 'M' and 'V' bits, and vendor_id field for this AVP.

`Parameters``:`

avpcode- AVP code

avpvalue- AVP value

is_mandatory- 'true' to set The 'M' bit in AVP

vendor_id- vendor_id field. non-zero vendor_id sets the 'V' bit and fills the vendor_id field in AVP as given.

`Returns:` text_t

`NEW_AVP_FLOAT32` (`uint` avpcode, unsigned_long_at avpvalue, bool_at is_mandatory, `uint` vendor_id)

Creates new AVP based on given avp code and given Float32 value. Set the 'M' and 'V' bits, and vendor_id field for this AVP.

`Parameters``:`

avpcode- AVP code

avpvalue- AVP value

is_mandatory- 'true' to set The 'M' bit in AVP

vendor_id- vendor_id field. non-zero vendor_id sets the 'V' bit and fills the vendor_id field in AVP as given.

`Returns:` text_t

`NEW_AVP_FLOAT64` (`uint` avpcode, double_at avpvalue)

Creates new AVP based on given avp code and given Float64 value. Vendor-Specific and Mandatory bit are not set.

`Parameters``:`

avpcode- AVP code

avpvalue- AVP value

`Returns:` text_t

`NEW_AVP_FLOAT64` (`uint` avpcode, ip_address_at avpvalue)

Creates new AVP based on given avp code and given Float64 value. Vendor-Specific and Mandatory bit are not set.

`Parameters``:`

avpcode- AVP code

avpvalue- AVP value

`Returns:` text_t

`NEW_AVP_FLOAT64` (`uint` avpcode, num_at avpvalue)

Creates new AVP based on given avp code and given Float64 value. Vendor-Specific and Mandatory bit are not set.

`Parameters``:`

avpcode- AVP code

avpvalue- AVP value

`Returns:` text_t

`NEW_AVP_FLOAT64` (`uint` avpcode, time_local_at avpvalue)

Creates new AVP based on given avp code and given Float64 value. Vendor-Specific and Mandatory bit are not set.

`Parameters``:`

avpcode- AVP code

avpvalue- AVP value

`Returns:` text_t

`NEW_AVP_FLOAT64` (`uint` avpcode, time_at avpvalue)

Creates new AVP based on given avp code and given Float64 value. Vendor-Specific and Mandatory bit are not set.

`Parameters``:`

avpcode- AVP code

avpvalue- AVP value

`Returns:` text_t

`NEW_AVP_FLOAT64` (`uint` avpcode, unsigned_long_at avpvalue)

Creates new AVP based on given avp code and given Float64 value. Vendor-Specific and Mandatory bit are not set.

`Parameters``:`

avpcode- AVP code

avpvalue- AVP value

`Returns:` text_t

`NEW_AVP_FLOAT64` (`uint` avpcode, double_at avpvalue, bool_at is_mandatory, `uint` vendor_id)

Creates new AVP based on given avp code and given Float64 value. Set the 'M' and 'V' bits, and vendor_id field for this AVP.

`Parameters``:`

avpcode- AVP code

avpvalue- AVP value

is_mandatory- 'true' to set The 'M' bit in AVP

vendor_id- vendor_id field. non-zero vendor_id sets the 'V' bit and fills the vendor_id field in AVP as given.

`Returns:` text_t

`NEW_AVP_FLOAT64` (`uint` avpcode, ip_address_at avpvalue, bool_at is_mandatory, `uint` vendor_id)

Creates new AVP based on given avp code and given Float64 value. Set the 'M' and 'V' bits, and vendor_id field for this AVP.

`Parameters``:`

avpcode- AVP code

avpvalue- AVP value

is_mandatory- 'true' to set The 'M' bit in AVP

vendor_id- vendor_id field. non-zero vendor_id sets the 'V' bit and fills the vendor_id field in AVP as given.

`Returns:` text_t

`NEW_AVP_FLOAT64` (`uint` avpcode, num_at avpvalue, bool_at is_mandatory, `uint` vendor_id)

Creates new AVP based on given avp code and given Float64 value. Set the 'M' and 'V' bits, and vendor_id field for this AVP.

`Parameters``:`

avpcode- AVP code

avpvalue- AVP value

is_mandatory- 'true' to set The 'M' bit in AVP

vendor_id- vendor_id field. non-zero vendor_id sets the 'V' bit and fills the vendor_id field in AVP as given.

`Returns:` text_t

`NEW_AVP_FLOAT64` (`uint` avpcode, time_local_at avpvalue, bool_at is_mandatory, `uint` vendor_id)

Creates new AVP based on given avp code and given Float64 value. Set the 'M' and 'V' bits, and vendor_id field for this AVP.

`Parameters``:`

avpcode- AVP code

avpvalue- AVP value

is_mandatory- 'true' to set The 'M' bit in AVP

vendor_id- vendor_id field. non-zero vendor_id sets the 'V' bit and fills the vendor_id field in AVP as given.

`Returns:` text_t

`NEW_AVP_FLOAT64` (`uint` avpcode, time_at avpvalue, bool_at is_mandatory, `uint` vendor_id)

Creates new AVP based on given avp code and given Float64 value. Set the 'M' and 'V' bits, and vendor_id field for this AVP.

`Parameters``:`

avpcode- AVP code

avpvalue- AVP value

is_mandatory- 'true' to set The 'M' bit in AVP

vendor_id- vendor_id field. non-zero vendor_id sets the 'V' bit and fills the vendor_id field in AVP as given.

`Returns:` text_t

`NEW_AVP_FLOAT64` (`uint` avpcode, unsigned_long_at avpvalue, bool_at is_mandatory, `uint` vendor_id)

Creates new AVP based on given avp code and given Float64 value. Set the 'M' and 'V' bits, and vendor_id field for this AVP.

`Parameters``:`

avpcode- AVP code

avpvalue- AVP value

is_mandatory- 'true' to set The 'M' bit in AVP

vendor_id- vendor_id field. non-zero vendor_id sets the 'V' bit and fills the vendor_id field in AVP as given.

`Returns:` text_t

`NEW_AVP_INTEGER32` (`uint` avpcode, num_at avpvalue)

Creates new AVP based on given avp code and given Integer32 value. Vendor-Specific and Mandatory bit are not set.

`Parameters``:`

avpcode- AVP code

avpvalue- AVP value

`Returns:` text_t

`NEW_AVP_INTEGER32` (`uint` avpcode, num_at avpvalue, bool_at is_mandatory, `uint` vendor_id)

Creates new AVP based on given avp code and given Integer32 value. Set the 'M' and 'V' bits, and vendor_id field for this AVP.

`Parameters``:`

avpcode- AVP code

avpvalue- AVP value

is_mandatory- 'true' to set The 'M' bit in AVP

vendor_id- vendor_id field. non-zero vendor_id sets the 'V' bit and fills the vendor_id field in AVP as given.

`Returns:` text_t

`NEW_AVP_INTEGER64` (`uint` avpcode, ip_address_at avpvalue)

Creates new AVP based on given avp code and given Integer64 value. Vendor-Specific and Mandatory bit are not set.

`Parameters``:`

avpcode- AVP code

avpvalue- AVP value

`Returns:` text_t

`NEW_AVP_INTEGER64` (`uint` avpcode, num_at avpvalue)

Creates new AVP based on given avp code and given Integer64 value. Vendor-Specific and Mandatory bit are not set.

`Parameters``:`

avpcode- AVP code

avpvalue- AVP value

`Returns:` text_t

`NEW_AVP_INTEGER64` (`uint` avpcode, time_local_at avpvalue)

Creates new AVP based on given avp code and given Integer64 value. Vendor-Specific and Mandatory bit are not set.

`Parameters``:`

avpcode- AVP code

avpvalue- AVP value

`Returns:` text_t

`NEW_AVP_INTEGER64` (`uint` avpcode, time_at avpvalue)

Creates new AVP based on given avp code and given Integer64 value. Vendor-Specific and Mandatory bit are not set.

`Parameters``:`

avpcode- AVP code

avpvalue- AVP value

`Returns:` text_t

`NEW_AVP_INTEGER64` (`uint` avpcode, unsigned_long_at avpvalue)

Creates new AVP based on given avp code and given Integer64 value. Vendor-Specific and Mandatory bit are not set.

`Parameters``:`

avpcode- AVP code

avpvalue- AVP value

`Returns:` text_t

`NEW_AVP_INTEGER64` (`uint` avpcode, ip_address_at avpvalue, bool_at is_mandatory, `uint` vendor_id)

Creates new AVP based on given avp code and given Integer64 value. Set the 'M' and 'V' bits, and vendor_id field for this AVP.

`Parameters``:`

avpcode- AVP code

avpvalue- AVP value

is_mandatory- 'true' to set The 'M' bit in AVP

vendor_id- vendor_id field. non-zero vendor_id sets the 'V' bit and fills the vendor_id field in AVP as given.

`Returns:` text_t

`NEW_AVP_INTEGER64` (`uint` avpcode, num_at avpvalue, bool_at is_mandatory, `uint` vendor_id)

Creates new AVP based on given avp code and given Integer64 value. Set the 'M' and 'V' bits, and vendor_id field for this AVP.

`Parameters``:`

avpcode- AVP code

avpvalue- AVP value

is_mandatory- 'true' to set The 'M' bit in AVP

vendor_id- vendor_id field. non-zero vendor_id sets the 'V' bit and fills the vendor_id field in AVP as given.

`Returns:` text_t

`NEW_AVP_INTEGER64` (`uint` avpcode, time_local_at avpvalue, bool_at is_mandatory, `uint` vendor_id)

Creates new AVP based on given avp code and given Integer64 value. Set the 'M' and 'V' bits, and vendor_id field for this AVP.

`Parameters``:`

avpcode- AVP code

avpvalue- AVP value

is_mandatory- 'true' to set The 'M' bit in AVP

vendor_id- vendor_id field. non-zero vendor_id sets the 'V' bit and fills the vendor_id field in AVP as given.

`Returns:` text_t

`NEW_AVP_INTEGER64` (`uint` avpcode, time_at avpvalue, bool_at is_mandatory, `uint` vendor_id)

Creates new AVP based on given avp code and given Integer64 value. Set the 'M' and 'V' bits, and vendor_id field for this AVP.

`Parameters``:`

avpcode- AVP code

avpvalue- AVP value

is_mandatory- 'true' to set The 'M' bit in AVP

vendor_id- vendor_id field. non-zero vendor_id sets the 'V' bit and fills the vendor_id field in AVP as given.

`Returns:` text_t

`NEW_AVP_INTEGER64` (`uint` avpcode, unsigned_long_at avpvalue, bool_at is_mandatory, `uint` vendor_id)

Creates new AVP based on given avp code and given Integer64 value. Set the 'M' and 'V' bits, and vendor_id field for this AVP.

`Parameters``:`

avpcode- AVP code

avpvalue- AVP value

is_mandatory- 'true' to set The 'M' bit in AVP

vendor_id- vendor_id field. non-zero vendor_id sets the 'V' bit and fills the vendor_id field in AVP as given.

`Returns:` text_t

`NEW_AVP` (`uint` avpcode, text_t avpvalue)

Creates new AVP based on given avp code and given value. Vendor-Specific and Mandatory bit are not set.

`Parameters``:`

avpcode- AVP code

avpvalue- AVP value as octet string

`Returns:` text_t

`NEW_AVP` (`uint` avpcode, text_t avpvalue, bool_at is_mandatory, `uint` vendor_id)

Creates new AVP based on given avp code and given value. Set the 'M' and 'V' bits, and vendor_id field for this AVP.

`Parameters``:`

avpcode- AVP code

avpvalue- AVP value as octet string

is_mandatory- 'true' to set The 'M' bit in AVP

vendor_id- vendor_id field. non-zero vendor_id sets the 'V' bit and fills the vendor_id field in AVP as given.

`Returns:` text_t

`NEW_AVP_UNSIGNED32` (`uint` avpcode, `uint` avpvalue)

Creates new AVP based on given avp code and given Unsigned32 value. Vendor-Specific and Mandatory bit are not set.

`Parameters``:`

avpcode- AVP code

avpvalue- AVP value

`Returns:` text_t

`NEW_AVP_UNSIGNED32` (`uint` avpcode, `uint` avpvalue, bool_at is_mandatory, `uint` vendor_id)

Creates new AVP based on given avp code and given Unsigned32 value. Set the 'M' and 'V' bits, and vendor_id field for this AVP.

`Parameters``:`

avpcode- AVP code

avpvalue- AVP value

is_mandatory- 'true' to set The 'M' bit in AVP

vendor_id- vendor_id field. non-zero vendor_id sets the 'V' bit and fills the vendor_id field in AVP as given.

`Returns:` text_t

`NEW_AVP_UNSIGNED64` (`uint` avpcode, ip_address_at avpvalue)

Creates new AVP based on given avp code and given Unsigned64 value. Vendor-Specific and Mandatory bit are not set.

`Parameters``:`

avpcode- AVP code

avpvalue- AVP value

`Returns:` text_t

`NEW_AVP_UNSIGNED64` (`uint` avpcode, num_at avpvalue)

Creates new AVP based on given avp code and given Unsigned64 value. Vendor-Specific and Mandatory bit are not set.

`Parameters``:`

avpcode- AVP code

avpvalue- AVP value

`Returns:` text_t

`NEW_AVP_UNSIGNED64` (`uint` avpcode, time_local_at avpvalue)

Creates new AVP based on given avp code and given Unsigned64 value. Vendor-Specific and Mandatory bit are not set.

`Parameters``:`

avpcode- AVP code

avpvalue- AVP value

`Returns:` text_t

`NEW_AVP_UNSIGNED64` (`uint` avpcode, time_at avpvalue)

Creates new AVP based on given avp code and given Unsigned64 value. Vendor-Specific and Mandatory bit are not set.

`Parameters``:`

avpcode- AVP code

avpvalue- AVP value

`Returns:` text_t

`NEW_AVP_UNSIGNED64` (`uint` avpcode, unsigned_long_at avpvalue)

Creates new AVP based on given avp code and given Unsigned64 value. Vendor-Specific and Mandatory bit are not set.

`Parameters``:`

avpcode- AVP code

avpvalue- AVP value

`Returns:` text_t

`NEW_AVP_UNSIGNED64` (`uint` avpcode, ip_address_at avpvalue, bool_at is_mandatory, `uint` vendor_id)

Creates new AVP based on given avp code and given Unsigned64 value. Set the 'M' and 'V' bits, and vendor_id field for this AVP.

`Parameters``:`

avpcode- AVP code

avpvalue- AVP value

is_mandatory- 'true' to set The 'M' bit in AVP

vendor_id- vendor_id field. non-zero vendor_id sets the 'V' bit and fills the vendor_id field in AVP as given.

`Returns:` text_t

`NEW_AVP_UNSIGNED64` (`uint` avpcode, num_at avpvalue, bool_at is_mandatory, `uint` vendor_id)

Creates new AVP based on given avp code and given Unsigned64 value. Set the 'M' and 'V' bits, and vendor_id field for this AVP.

`Parameters``:`

avpcode- AVP code

avpvalue- AVP value

is_mandatory- 'true' to set The 'M' bit in AVP

vendor_id- vendor_id field. non-zero vendor_id sets the 'V' bit and fills the vendor_id field in AVP as given.

`Returns:` text_t

`NEW_AVP_UNSIGNED64` (`uint` avpcode, time_local_at avpvalue, bool_at is_mandatory, `uint` vendor_id)

Creates new AVP based on given avp code and given Unsigned64 value. Set the 'M' and 'V' bits, and vendor_id field for this AVP.

`Parameters``:`

avpcode- AVP code

avpvalue- AVP value

is_mandatory- 'true' to set The 'M' bit in AVP

vendor_id- vendor_id field. non-zero vendor_id sets the 'V' bit and fills the vendor_id field in AVP as given.

`Returns:` text_t

`NEW_AVP_UNSIGNED64` (`uint` avpcode, time_at avpvalue, bool_at is_mandatory, `uint` vendor_id)

Creates new AVP based on given avp code and given Unsigned64 value. Set the 'M' and 'V' bits, and vendor_id field for this AVP.

`Parameters``:`

avpcode- AVP code

avpvalue- AVP value

is_mandatory- 'true' to set The 'M' bit in AVP

vendor_id- vendor_id field. non-zero vendor_id sets the 'V' bit and fills the vendor_id field in AVP as given.

`Returns:` text_t

`NEW_AVP_UNSIGNED64` (`uint` avpcode, unsigned_long_at avpvalue, bool_at is_mandatory, `uint` vendor_id)

Creates new AVP based on given avp code and given Unsigned64 value. Set the 'M' and 'V' bits, and vendor_id field for this AVP.

`Parameters``:`

avpcode- AVP code

avpvalue- AVP value

is_mandatory- 'true' to set The 'M' bit in AVP

vendor_id- vendor_id field. non-zero vendor_id sets the 'V' bit and fills the vendor_id field in AVP as given.

`Returns:` text_t

- `NEW_ERROR_ANSWER`

  Creates new Diameter Error Response Message (Header only) based on Request header.

`Returns:` text_t

`NEW_REDIRECT` (text_t redirectUri)

Creates new Diameter Redirect Response Message (Header only) based on Request header. This Redirect message will not have Redirect-Host-Usage and Redirect-Max-Cache-Time AVP.

`Parameters` (expressions not allowed)`:`

redirectUri- Redirect-Host AVP value

`Returns:` text_t

`NEW_REDIRECT` (text_t redirectUri, `uint` hostUsage, `uint` maxCacheTime)

Creates new Diameter Redirect Response Message (Header only) based on Request header. Use hostUsage and maxCacheTime parameters to insert Redirect-Host-Usage and Redirect-Max-Cache-Time AVP as defined in RFC 6733 section-6.13 (http://tools.ietf.org/md/rfc6733#section-6.13)

`Parameters` (expressions not allowed)`:`

redirectUri- Redirect-Host AVP value

hostUsage- Redirect-Host-Usage AVP value

maxCacheTime- Redirect-Max-Cache-Time AVP value.

`Returns:` text_t

- `REQ`

  Retrieves header information and AVPs from Diameter requests.

`Returns:` diameter_req_t

- `RES`

  Retrieves header information and AVPs from Diameter responses.

`Returns:` diameter_res_t

DIAMETER_REQ_T

Retrieves header information and AVPs from Diameter requests.

AVPs can be retrieved by:

- Directly specifying the AVP codes in the form: DIAMETER.REQ.AVP( ). For example, to retrieve the Auth-Application-Id AVP (code 258), you can use the expression: DIAMETER.REQ.AVP(258).
- Using aliases that are provided for important AVPs. For example, the Auth-Application-Id AVP has the alias AUTH_APPLICATION_ID. So, the expression to retrieve the Auth-Application-Id AVP by using the alias is DIAMETER.REQ.AUTH_APPLICATION_ID.

`General usage:` DIAMETER.REQ.

This topic lists the expressions that are provided by this class.

`*Note` *: Expressions with the * symbol are inherited / promoted from diameter_message_t

- `DESTINATION_HOST`

  Returns the Destination-Host AVP (code 293) from the request.

`Returns:` avp_t

`*DESTINATION_REALM`

Returns the Destination-Realm AVP (code 283) from the request.

`Returns:` avp_t

`*IS_RETRANSMIT`

Returns true if the T (potentially retransmitted message) command flag is set for the request.

`Returns:` bool_at

`*TYPECAST_DIAMETER_MESSAGE_T`

Convert diameter_req_t to diameter_message_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (diameter_message_t : Define common operations for Diameter.Req or Diameter.Res.)

`Returns:` diameter_message_t

`*ACCOUNTING_SUB_SESSION_ID`

Returns the Accounting-Sub-Session-Id AVP (code 287) from the message.

`Returns:` avp_t

`*ACCT_APPLICATION_ID`

Returns the Acct-Application-Id AVP (code 259) from the message. `Note:` expression can be used to retrieve the value as Unsigned32

`Returns:` avp_unum_t

`*ACCT_MULTI_SESSION_ID`

Returns the Acct-Multi-Session-Id AVP (code 50) from the message.

`Returns:` avp_t

`*ACCT_SESSION_ID`

Returns the Acct-Session-ID AVP (code 44) from the message.

`Returns:` avp_t

`*APPLICATION_ID`

Returns the Application-ID from the message.

`Returns:` unum_text_t

`*AUTH_APPLICATION_ID`

Returns the Auth-Application-Id AVP (code 258) from the message. `Note:` expression can be used to retrieve the value as Unsigned32

`Returns:` avp_unum_t

`*AVP_END`

Returns the location at the end of Diameter message (or in other words end of all AVPs) in Diameter message.

`Returns:` text_t

`*AVP_LIST`

Returns the AVP region in Diameter message (or in other words returns location at start of AVPs and length equal to Diameter message length excluding header).

`Returns:` text_t

`*AVP` (`uint` avpcode)

Returns the specified AVP from the message.

For example, to get the AVP with code 263 from a Request, use the expression: DIAMETER.REQ.AVP(263).

`Note:` To get AVP that is nested inside a grouped AVP, use the AVP method from the avp_t class.

`Parameters` (expressions not allowed) `:`

avpcode- AVP code

`Returns:` avp_t

`*AVP` (`uint` avpcode, `uint` vendorid)

Returns the specified AVP in given vendor-id namespace from the message.

For example, to get the AVP with code 1001 and VendorId 10415 from a Request, use the expression: DIAMETER.REQ.AVP(1001, 10415).

`Note:` To get AVP that is nested inside a grouped AVP, use the AVP method from the avp_t class.

`Parameters` (expressions not allowed) `:`

avpcode- AVP code

vendorid- Vendor Id

`Returns:` avp_t

`*AVP_START`

Returns the location at the start of AVPs (or in other words end of diameter header) in Diameter message.

`Returns:` text_t

`*COMMAND_CODE`

Returns the Command Code from the message.

`Returns:` unum_text_t

`*END_TO_END_ID`

Returns the End-to-End Identifier from the message.

`Returns:` unsigned_long_at

`*FLAGS`

Returns the value of Diameter Header flags in Diameter message.

`Returns:` diameter_flag_t

`*HOP_BY_HOP_ID`

Returns the Hop-by-Hop Identifier from the message.

`Returns:` unsigned_long_at

`*IS_PROXIABLE`

Returns true if the P (proxiable) command flag is set for the message.

`Returns:` bool_at

`*LENGTH`

Returns the Message Length from the message.

`Returns:` num_at

`*ORIGIN_HOST`

Returns the Origin-Host AVP (code 264) from the message.

`Returns:` avp_t

`*ORIGIN_REALM`

Returns the Origin-Realm AVP (code 296) from the message.

`Returns:` avp_t

`*PRODUCT_NAME`

Returns the Product-Name AVP (code 269) from the message.

`Returns:` avp_t

`*SESSION_ID`

Returns the Session-ID AVP (code 263) from the message.

`Returns:` avp_t

`*SUPPORTED_VENDOR_ID`

Returns the Supported-Vendor-Id AVP (code 265) from the message.

`Returns:` avp_t

`*USER_NAME`

Returns the User-Name AVP (code 1) from the message.

`Returns:` avp_t

`*VENDOR_ID`

Returns the Vendor-Id AVP (code 266) from the message.

`Returns:` avp_t

`*VENDOR_SPECIFIC_APPLICATION_ID`

Returns the Vendor-Specific-Application-Id AVP (code 260) from the message.

`Returns:` vendor_spec_appid_avp_t

`*VERSION`

Returns the version of the Diameter protocol. Currently, Diameter supports only version 1.

`Returns:` unum_text_t

DIAMETER_RES_T

Retrieves header information and AVPs from Diameter responses.

AVPs can be retrieved by:

- Directly specifying the AVP codes in the form: DIAMETER.RES.AVP( ). For example, to retrieve the Auth-Application-Id AVP (code 258), you can use the expression: DIAMETER.RES.AVP(258).
- Using aliases that are provided for important AVPs. For example, the Auth-Application-Id AVP has the alias AUTH_APPLICATION_ID. So, the expression to retrieve the Auth-Application-Id AVP by using the alias is DIAMETER.RES.AUTH_APPLICATION_ID.

`General usage:` DIAMETER.RES.

This topic lists the expressions that are provided by this class.

`*Note` *: Expressions with the * symbol are inherited / promoted from diameter_message_t

- `IS_ERROR`

  Returns true if the E (error) command flag is set for the response.

`Returns:` bool_at

`*REDIRECT_HOST`

Returns the Redirect-Host AVP (code 292) from the response.

`Returns:` avp_t

`*RESULT_CODE`

Returns the Result-Code AVP (code 268) from the response.

`Returns:` avp_t

`*TYPECAST_DIAMETER_MESSAGE_T`

Convert diameter_res_t to diameter_message_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (diameter_message_t : Define common operations for Diameter.Req or Diameter.Res.)

`Returns:` diameter_message_t

`*ACCOUNTING_SUB_SESSION_ID`

Returns the Accounting-Sub-Session-Id AVP (code 287) from the message.

`Returns:` avp_t

`*ACCT_APPLICATION_ID`

Returns the Acct-Application-Id AVP (code 259) from the message. `Note:` expression can be used to retrieve the value as Unsigned32

`Returns:` avp_unum_t

`*ACCT_MULTI_SESSION_ID`

Returns the Acct-Multi-Session-Id AVP (code 50) from the message.

`Returns:` avp_t

`*ACCT_SESSION_ID`

Returns the Acct-Session-ID AVP (code 44) from the message.

`Returns:` avp_t

`*APPLICATION_ID`

Returns the Application-ID from the message.

`Returns:` unum_text_t

`*AUTH_APPLICATION_ID`

Returns the Auth-Application-Id AVP (code 258) from the message. `Note:` expression can be used to retrieve the value as Unsigned32

`Returns:` avp_unum_t

`*AVP_END`

Returns the location at the end of Diameter message (or in other words end of all AVPs) in Diameter message.

`Returns:` text_t

`*AVP_LIST`

Returns the AVP region in Diameter message (or in other words returns location at start of AVPs and length equal to Diameter message length excluding header).

`Returns:` text_t

`*AVP` (`uint` avpcode)

Returns the specified AVP from the message.

For example, to get the AVP with code 263 from a Request, use the expression: DIAMETER.REQ.AVP(263).

`Note:` To get AVP that is nested inside a grouped AVP, use the AVP method from the avp_t class.

`Parameters` (expressions not allowed) `:`

avpcode- AVP code

`Returns:` avp_t

`*AVP` (`uint` avpcode, `uint` vendorid)

Returns the specified AVP in given vendor-id namespace from the message.

For example, to get the AVP with code 1001 and VendorId 10415 from a Request, use the expression: DIAMETER.REQ.AVP(1001, 10415).

`Note:` To get AVP that is nested inside a grouped AVP, use the AVP method from the avp_t class.

`Parameters` (expressions not allowed) `:`

avpcode- AVP code

vendorid- Vendor Id

`Returns:` avp_t

`*AVP_START`

Returns the location at the start of AVPs (or in other words end of diameter header) in Diameter message.

`Returns:` text_t

`*COMMAND_CODE`

Returns the Command Code from the message.

`Returns:` unum_text_t

`*END_TO_END_ID`

Returns the End-to-End Identifier from the message.

`Returns:` unsigned_long_at

`*FLAGS`

Returns the value of Diameter Header flags in Diameter message.

`Returns:` diameter_flag_t

`*HOP_BY_HOP_ID`

Returns the Hop-by-Hop Identifier from the message.

`Returns:` unsigned_long_at

`*IS_PROXIABLE`

Returns true if the P (proxiable) command flag is set for the message.

`Returns:` bool_at

`*LENGTH`

Returns the Message Length from the message.

`Returns:` num_at

`*ORIGIN_HOST`

Returns the Origin-Host AVP (code 264) from the message.

`Returns:` avp_t

`*ORIGIN_REALM`

Returns the Origin-Realm AVP (code 296) from the message.

`Returns:` avp_t

`*PRODUCT_NAME`

Returns the Product-Name AVP (code 269) from the message.

`Returns:` avp_t

`*SESSION_ID`

Returns the Session-ID AVP (code 263) from the message.

`Returns:` avp_t

`*SUPPORTED_VENDOR_ID`

Returns the Supported-Vendor-Id AVP (code 265) from the message.

`Returns:` avp_t

`*USER_NAME`

Returns the User-Name AVP (code 1) from the message.

`Returns:` avp_t

`*VENDOR_ID`

Returns the Vendor-Id AVP (code 266) from the message.

`Returns:` avp_t

`*VENDOR_SPECIFIC_APPLICATION_ID`

Returns the Vendor-Specific-Application-Id AVP (code 260) from the message.

`Returns:` vendor_spec_appid_avp_t

`*VERSION`

Returns the version of the Diameter protocol. Currently, Diameter supports only version 1.

`Returns:` unum_text_t

DIGEST_METHOD_E

Defines the message digest methods allowed in DIGEST().

SHA256

SHA384

SHA512

DNS_DOMAINNAME_T

This object provides operations for parsing the DNS domain name as it appears at various places in the DNS data. The format is abc.foo.com.

This topic lists the expressions that are provided by this class.

`*Note` *: Expressions with the * symbol are inherited / promoted from text_t

`EQ` (text_t hostname)

Operates on the text contents of domainname. Results in Boolean TRUE value if the domainname matches the input argument. The comparison will be case-insensitive: if the domain name is "www.ForBar.com" then CLIENT.UDP.DNS.DOMAIN.EQ("www.forbar.com") returns TRUE. Similarly for DNS.REQ.QUESTION.DOMAIN.EQ("www.forbar.com").

`Parameters``:`

hostname- Hostname

`Returns:` bool_at

`*TYPECAST_TEXT_T`

Convert dns_domainname_t to text_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (text_t : Designates any piece of text.)

`Returns:` text_t

`*AFTER_REGEX` (`re` regex)

Selects the text after the portion that matches the given regular expression argument. The first match is returned when multiple matches occur in the text. The match may occur anywhere within the text - if you wish to "anchor" this, use "\^" at the start of the regex and/or "$" at the end of the regex. When the regular expression does not match the given string, a Text object of length of 0 is returned.

Example: HTTP.REQ.HEADER("etag").AFTER_REGEX(re/KX/) will select "DAPPER" from "KXDAPPER". This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

regex- Regular Expression

`Returns:` text_t

`*AFTER_STR_ANY` (text_t patset_name)

Selects the Text that is present after the first occurrence of any of the strings that are bound to the patset named by the string argument. If there is no match to any of the strings bound to the patset in the current Text object then the result Text object has 0 length. The patset cannot have strings longer than 255 characters. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` text_t

`*AFTER_STR` (text_t s)

Selects the Text that is present after the first occurrence of the string argument. If there is no match for the argument in the current Text then the result Text object has 0 length. The input string cannot be bigger than 255 characters. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*APPEND` (bool_at b)

Appends the given boolean's string representation to the current string.

`Parameters``:`

b- the boolean value to append.

`Returns:` text_t

`*APPEND` (double_at i)

Appends the given double's string representation to the current string.

`Parameters``:`

i- the double value to append.

`Returns:` text_t

`*APPEND` (ip_address_at addr)

Appends the given IPv4's string representation to the current string.

`Parameters``:`

addr- the IPv4 address to append.

`Returns:` text_t

`*APPEND` (num_at i)

Appends the given number's string representation to the current string.

`Parameters``:`

i- the number value to append.

`Returns:` text_t

`*APPEND` (time_local_at t)

Appends the given time's string representation to the current string.

`Parameters``:`

t- the time value to append.

`Returns:` text_t

`*APPEND` (time_at t)

Appends the given time's string representation to the current string.

`Parameters``:`

t- the time value to append.

`Returns:` text_t

`*APPEND` (unsigned_long_at i)

Appends the given unsigned long's string representation to the current string.

`Parameters``:`

i- the unsigned long value to append.

`Returns:` text_t

`*APPEND` (ipv6_address_at addr)

Appends the given IPv6's string representation to the current string.

`Parameters``:`

addr- the IPv6 address to append.

`Returns:` text_t

`*APPEND` (ipv6_subnet_at addr)

Appends the given IPv6 subnet's string representation to the current string.

`Parameters``:`

addr- the IPv6 subnet to append.

`Returns:` text_t

`*APPEND` (mac_address_at addr)

Appends the given MAC's string representation to the current string.

`Parameters``:`

addr- the MAC address to append.

`Returns:` text_t

`*APPEND` (text_t str)

Appends the given string to the current string.

`Parameters``:`

str- the string to append.

`Returns:` text_t

`*APPEND` (time_at t)

Appends the given time's string representation to the current string.

`Parameters``:`

t- the time value to append.

`Returns:` text_t

`*B64DECODE`

Decodes the selected text using base64 decoding.

For example, the string "TWFu" is converted to "Man"

`Returns:` text_t

`*B64ENCODE`

Encodes the selected text using base64 encoding.

For example, the string "Man" is converted to "TWFu"

`Returns:` text_t

`*BEFORE_REGEX` (`re` regex)

Selects the text before the portion that matches the given regular expression argument. The first match is returned when multiple matches occur in the text. The match may occur anywhere within the text - if you wish to "anchor" this, use "\^" at the start of the regex and/or "$" at the end of the regex. When the regular expression does not match the given string, a Text object of length of 0 is returned.

For example: HTTP.RES.HEADER("content-type").BEFORE_REGEX(re#/#) will select "text" from "text/plain". This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

regex- Regular Expression

`Returns:` text_t

`*BEFORE_STR_ANY` (text_t patset_name)

Selects the Text that is present before the first occurrence of any of the strings that are bound to the patset or datasetnamed by the string argument. If there is no match to any of the strings bound to the patset in the current Text object then the result Text object has 0 length. The patset cannot have strings longer than 255 characters. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` text_t

`*BEFORE_STR` (text_t s)

Selects the Text that is present before the first occurrence of the string argument. If there is no match for the argument in the current Text object then the result Text object has 0 length. The input string cannot be bigger than 255 characters. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*BETWEEN` (text_t start, text_t end)

Results in Boolean TRUE value if length of the Text object is greater than or equal to the sum of the Start and End argument lengths and if the prefix of the Text object matches the Start string argument and if the Suffix of the Text object matches the End string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

start- Start

end- End

`Returns:` bool_at

`*BIN_DECODE` (binary_encoding_e encoding)

Decode the encoded input into its original byte sequence. An incorrectly enooded input will result in an Undef error.

`Parameters` (expressions not allowed) `:`

encoding- specifies how the bytes are encoded.

`Returns:` text_t

`*BIN_ENCODE` (binary_encoding_e encoding)

Encode the input byte sequence. Note that BIN_ENCODE(hex_colons) is equivalent to BLOB_TO_HEX().

`Parameters` (expressions not allowed) `:`

encoding- specifies how the bytes are to be encoded.

`Returns:` text_t

`*BLOB_TO_HEX`

Convert to hexadecimal representation and select text.

For example, the byte string abc is converted to 61:62:63.

`Returns:` text_t

`*COMPARE` (text_t s)

Results in a Number Value which is the result of comparison of the input argument with the Text object. The result is greater than 0 if the Text object is lexicographically greater than the argument. The result is 0 if the Text object and the argument match. The result is less than 0 if the Text object is lexicographically lesser than the argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` num_at

`*CONTAINS_ANY` (text_t patset_name)

Results in Boolean TRUE value if the Text contains any of the strings that are bound to the patset or dataset named by the string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` bool_at

`*CONTAINS_INDEX` (text_t patset_name)

Returns the numerical index of the matching string, if the Text contains any of the strings that are bound to the patset or dataset named by the string argument. Returns 0 if there is no match. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` num_at

`*CONTAINS` (text_t s)

Results in Boolean TRUE value if the Text contains the string given in the argument. The input string cannot be bigger than 255 characters. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*CRC32`

Returns a 32-bit integer computed by applying a CRC (cyclic redundancy check) function to the selected text. This is the CRC function used by Ethernet, MPEG-2, PKZIP, GZIP, PNG, and many other applications. For example, the expression to compute the CRC value of the (first 1000 bytes of the) body of an HTTP request is: HTTP.REQ.BODY(1000).CRC32

`Returns:` num_at

`*DECODE_USING_TEXT_MODE`

Decodes the selected text using the currently configured text encoding methods like URLENCODED, BACKSLASH_ENCODED, PLUS_AS_SPACE, NOURLENCODED,

NO_BACKSLASH_ENCODED and NO_PLUS_AS_SPACE. Text encoding methods are set using SET_TEXT_MODE method.

`Returns:` text_t

`*DECRYPT`

Decrypt the selected base64-encoded ciphertext using the configured encryptionParams.

`Returns:` text_t

`*DECRYPT` (binary_encoding_e in_encoding)

Decrypt the selected ciphertext using the configured encryptionParams.

`Parameters` (expressions not allowed) `:`

in_encoding- specifies how the input ciphertext is encoded. If the ciphertext is not encoded as specified, causes an Undef error.

`Returns:` text_t

`*DECRYPT` (text_t encryptionKey)

Decrypt the selected base64-encoded encrypted bytes using the configured encryption key.

`Parameters` (expressions not allowed) `:`

encryptionKey- identifies the encryptionKey object to provide the cipher method, mode, padding, key, encrypted format and optional initialization vector (IV).

`Returns:` text_t

`*DECRYPT` (text_t encryptionKey, binary_encoding_e in_encoding)

Decrypt the selected base64-encoded encrypted bytes using the configured encryption key.

`Parameters` (expressions not allowed) `:`

encryptionKey- identifies the encryptionKey object to provide the cipher method, mode, padding, key, encrypted format, and optional initialization vector (IV).

in_encoding- specifies how the input ciphertext is encoded. If the ciphertext is not encoded as specified, causes an Undef error.

`Returns:` text_t

`*DIGEST` (digest_method_e method)

Returns a byte sequence computed by applying the the specified message digest method to the selected text.

`Parameters` (expressions not allowed) `:`

method- digest method to apply to the input text

`Returns:` text_t

`*ENCRYPT`

Encrypt the selected plaintext bytes using the configured encryptionParams. The resulting ciphertext is base64-encoded.

`Returns:` text_t

`*ENCRYPT` (binary_encoding_e out_encoding)

Encrypt the selected plaintext bytes using the configured encryptionParams.

`Parameters` (expressions not allowed) `:`

out_encoding- specifies how the resulting ciphertext is encoded.

`Returns:` text_t

`*ENCRYPT` (text_t encryptionKey)

Encrypt the selected cleartext bytes using the configured encryption key.

`Parameters` (expressions not allowed) `:`

encryptionKey- identifies the encryptionKey object to provide the cipher method, mode, padding, key, encrypted format and optional initialization vector (IV).

`Returns:` text_t

`*ENCRYPT` (text_t encryptionKey, binary_encoding_e out_encoding)

Encrypt the selected cleartext bytes using the configured encryption key.

`Parameters` (expressions not allowed) `:`

encryptionKey- identifies the encryptionKey object to provide the cipher method, mode, padding, key, encrypted format and optional initialization vector (IV).

out_encoding- specifies how the resulting ciphertext is encoded.

`Returns:` text_t

`*ENDSWITH_ANY` (text_t patset_name)

Results in Boolean TRUE value if the Text ends with any of the strings that are bound to the patset or dataset named by the string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` bool_at

`*ENDSWITH_INDEX` (text_t patset_name)

Returns the numerical index of the matching string, if the Text ends with any of the strings that are bound to the patset or dataset named by the string argument. Returns 0 if there is no match. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` num_at

`*ENDSWITH` (text_t end)

Results in Boolean TRUE value if a suffix of the Text object matches the string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

end- String

`Returns:` bool_at

`*EQUALS_ANY` (text_t patset_name)

Results in Boolean TRUE value if the Text equals any of the strings that are bound to the patset or dataset named by the string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` bool_at

`*EQUALS_INDEX` (text_t patset_name)

Returns the numerical index of the matching string, if the Text equals any of the strings that are bound to the patset or dataset named by the string argument. Returns 0 if there is no match. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` num_at

`*GET_SIGNED16` (`uint` n, endian_e endianness)

Get the 16-bit signed binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

endianness- Select little or big endian

`Returns:` num_at

`*GET_SIGNED32` (`uint` n, endian_e endianness)

Get the 32-bit signed binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

endianness- Select little or big endian

`Returns:` num_at

`*GET_SIGNED8` (`uint` n)

Get the 8-bit signed binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

`Returns:` num_at

`*GET_UNSIGNED16` (`uint` n, endian_e endianness)

Get the 16-bit unsigned binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

endianness- Select little or big endian

`Returns:` num_at

`*GET_UNSIGNED32` (`uint` n, endian_e endianness)

Get the 32-bit unsigned binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

endianness- Select little or big endian

`Returns:` unsigned_long_at

`*GET_UNSIGNED64` (`uint` n, endian_e endianness)

Get the 64-bit unsigned binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

endianness- Select little or big endian

`Returns:` unsigned_long_at

`*GET_UNSIGNED8` (`uint` n)

Get the 8-bit unsigned binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

`Returns:` num_at

`*GET_URLSET_METADATA` (text_t urlset_name)

Returns metadata value corresponding to pattern in the urlset. The matching is case-insensitive for domains, but case-sensitive for paths. If no pattern is matched within the urlset, the return value is a NULL string. For example:

- HTTP.REQ.HOST.APPEND(HTTP.REQ.URL).GET_URLSET_METADATA("urlset_forbidden") returns value when the combined domain and URL is looked up in the urlset whose name is "urlset_forbidden".

`Parameters` (expressions not allowed)`:`

urlset_name- urlset name

`Returns:` text_t

`*GE` (text_t s)

Results in Boolean TRUE value if the Text object is greater than or equal to the input argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*GRPC`

Interprets a text_t string as a Protocol Buffer (protocol_buffer_t type). Example: HTTP.REQ.BODY(1000).GRPC.STRING(1).EQ("bookname")

`Returns:` protocol_buffer_t

`*GT` (text_t s)

Results in Boolean TRUE value if the Text object is greater than the input argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*HASH`

Returns a positive 31 bit integer value computed by applying a proprietary NetScaler hash function to the selected text. This function is not case- sensitive and ignores whitespaces. For example, applying the HASH function to two strings "Ab c" and "abc" would produce the same value. This function should not be used for security purposes; use instead the DIGEST function with one of the standard digest methods.

`Returns:` num_at

`*HMAC` (text_t hmacKey)

Returns a byte sequence computed by applying the HMAC (Hash Message Authenticastion Code) function to the selected text using the configured HMAC key.

`Parameters` (expressions not allowed)`:`

hmacKey- indentifies the hmacKey object to provide the digest (hash) method and the key.

`Returns:` text_t

`*HMAC` (text_t hmacKey, binary_encoding_e out_encoding)

Returns a byte sequence computed by applying the HMAC (Hash Message Authenticastion Code) function to the selected text using the configured HMAC key .

`Parameters` (expressions not allowed)`:`

hmacKey- indentifies the hmacKey object to provide the digest (hash) method and the key.

out_encoding- specifies how the resulting HMAC is encoded.

`Returns:` text_t

`*HTML_XML_SAFE`

Apply XML safe transform and select text.

Converts '<', '>' and '&' in the input text to '<', '>' and '&' respectively; other characters in the input are not modified. This transform safeguards against XSS based attacks. This is a read only operation.

`Returns:` text_t

`*HTTP_HEADER_SAFE`

Apply Header safe transform and select text. Converts all new line ('\\n') characters present in the input text to '%0A' so that they can safely be used in HTTP headers. This transform safeguards against response-splitting attacks. This is a read only operation.

`Returns:` text_t

`*HTTP_URL_SAFE`

Apply URL safe transform and select text. Converts URL unsafe characters to corresponding '%xx' values and retains the rest. This is a read only operation.

```
Based on RFC2396, following are considered URL safe characters:

    Alpha-numeric characters: a-z, A-Z, 0-9

    Hyphen and underscore: "-", "_"

    Dot: "."

    Exclamation mark: "!"

    Tilde: "~"

    Asterix: "&ast;"

    Single quote: "'"

    Open and close parentheses: "(", ")"

    Semi-colon: ";"

    Colon: ":"
```

```
    At symbol: "@"

    Question mark: "?"

    Equals: "="

    Dollar: "$"

    Percent: "%"

    Ampersand: "&"

    Plus: "+"

    Comma: ","

    Forward slash: ".html"
```

The rest are converted to %XX encoding, 'XX' is the hex-based representation of the input character. If the requirement is to encode all but URL unreserved characters, please consider using URL_RESERVED_CHARS_SAFE method.

`Returns:` text_t

`*IS_BOOL_AT`

Results in Boolean TRUE value if the Text is of boolean type.

`Returns:` bool_at

`*IS_DOUBLE_AT`

Results in Boolean TRUE value if the Text is of double data type.

`Returns:` bool_at

`*IS_IPV6_AT`

Results in Boolean TRUE value if the Text is of IPv6 data type.

`Returns:` bool_at

`*IS_IPV6_SUBNET_AT`

Results in Boolean TRUE value if the Text is of IPv6 subnet data type.

`Returns:` bool_at

`*IS_IP_AT`

Results in Boolean TRUE value if the Text is of IPv4 data type.

`Returns:` bool_at

`*IS_MAC_ADDRESS_AT`

Results in Boolean TRUE value if the Text is of mac address data type.

`Returns:` bool_at

`*IS_NUM_AT`

Results in Boolean TRUE value if the Text is of number type.

`Returns:` bool_at

`*IS_NUM_AT` (num_format_e format)

Results in Boolean TRUE value if the Text is of number type with given input base.

`Parameters` (expressions not allowed) `:`

format- number format

`Returns:` bool_at

`*IS_STRINGMAP_KEY` (text_t string_map_name)

Returns true if the string that it operates on is present in the string map. Text mode IGNORECASE, NOIGNORECASE - controls whether key lookup in string map is case sensitive or not. For example:

- HTTP.REQ.URL.IS_STRINGMAP_KEY("url_stringmap") returns true if value of HTTP.REQ.URL is present as key in the string map whose name is "url_stringmap".
- HTTP.REQ.URL.SET_TEXT_MODE(IGNORECASE). IS_STRINGMAP_KEY("url_stringmap") returns true if value of HTTP.REQ.URL is present as key in the string map whose name is "url_stringmap". Key lookup in this case is done case-insensitively.

`Parameters` (expressions not allowed) `:`

string_map_name- identifies the string map.

`Returns:` bool_at

`*IS_TIME_AT`

Results in Boolean TRUE if the Text follows any of the standard time formats given below, otherwise false. Tue, 05 Nov 1994 08:12:31 GMT RFC822 Tuesday, 05-Nov-94 08:12:31 GMT RFC850 Tue Nov 4 08:12:31 1994 asctime

`Returns:` bool_at

`*IS_UNSIGNED_LONG_AT`

Results in Boolean TRUE value if the Text is of unsigned long data type.

`Returns:` bool_at

`*IS_UNSIGNED_LONG_AT` (num_format_e format)

Results in Boolean TRUE value if the Text is of unsigned long data type with given input base.

`Parameters` (expressions not allowed) `:`

format- number format

`Returns:` bool_at

`*JWT_VERIFY_CERTKEY` (text_t certkey_name)

Verifies the signature on the input JSON Web Token (JWT), using the RSA public key in the X.509 certificate in the specified certkey object. The token has the format HEADER.PAYLOAD.SIGNATURE where

- HEADER is a base64-encoded JSON structure indicating a signature algorithm and token type, e.g.'{"alg":"RS256","typ":"JWT"}'
- PAYLOAD is a base64-encoded JSON structure with asserted claims, e.g. '{"loggedInAs":"admin","iat":1422779638}'
- SIGNATURE is the base64-encoded bytes for the signature on HEADER.PAYLOAD.

Returns true if the signature is verified for the header and payload using the specified public key; false if the signature is not verified

`Parameters``:`

certkey_name- identifies the certkey object containing an X.509 certificate holding the RSA public key. Results in an Undef error if the certkey object does not exist or does not contain an X.509 certificate with an RSA public key, if the token is not correctly formatted, or if the verification operation cannot complete.

`Returns:` bool_at

`*JWT_VERIFY_XML` (text_t xml_pkey)

Verifies the signature on the input JSON Web Token (JWT), using the RSA public key supplied by the specified XML element. The token has the format HEADER.PAYLOAD.SIGNATURE where

- HEADER is a base64-encoded JSON structure indicating a signature algorithm and token type, e.g.'{"alg":"RS256","typ":"JWT"}'
- PAYLOAD is a base64-encoded JSON structure with asserted claims, e.g. '{"loggedInAs":"admin","iat":1422779638}'
- SIGNATURE is the base64-encoded bytes for the signature on HEADER.PAYLOAD.

Returns true if the signature is verified for the header and payload using the specified public key; false if the signature is not verified

`Parameters``:`

xml_pkey- an expression that supplies an <RSAKeyValue> element with the public key. Results in an Undef error if the XML element is invalid or does not correctly specify an RSA public key, if the token is not correctly formatted, or if the verification operation cannot complete.

`Returns:` bool_at

`*LENGTH`

Results in a Number Value that is the number of characters (not bytes) in the Text object.

`Returns:` num_at

`*LE` (text_t s)

Results in Boolean TRUE value if the Text object is less than or equal to the input argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*LOCATION_LONG`

Get the location qualifier from CLIENT.IP.SRC.LOCATION.GET(n) (ISO short name) and then convert it to human readable long name. This conversion is valid only for country names. Correct Country qualifier value (number) in GET(n) is left up to the user as qualifiers are user configurable. Expression example: CLIENT.IP.SRC.LOCATION.GET(1).LOCATION_LONG For example: Data from each expression CLIENT.IP.SRC.LOCATION: NA.US.California.SantaClara.*.* CLIENT.IP.SRC.LOCATION.GET(1): US CLIENT.IP.SRC.LOCATION.GET(1).LOCATION_LONG: United States

`Returns:` text_t

`*LT` (text_t s)

Results in Boolean TRUE value if the Text object is less than the input argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*MAP_STRING_DEFAULT_TO_KEY` (text_t string_map_name)

Returns the value corresponding to the key in the string map. This is similar to the MAP_STRING method, but if the key is not present then instead of returning a null string, it returns the key itself. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

string_map_name- identifies the string map.

`Returns:` text_t

`*MAP_STRING` (text_t string_map_name)

Returns value corresponding to key in the string map. Key is the string that it is given as input. Text mode IGNORECASE, NOIGNORECASE - controls whether key lookup in string map is case sensitive or not. For example:

- HTTP.REQ.URL.MAP_STRING("url_stringmap") returns value when the value of HTTP.REQ.URL is used as key in the string map whose name is "url_stringmap".
- HTTP.REQ.URL.SET_TEXT_MODE(IGNORECASE). MAP_STRING("url_stringmap") returns value when the value of HTTP.REQ.URL is used as key in the string map whose name is "url_stringmap". Key lookup in this case is done case-insensitively.

`Parameters` (expressions not allowed) `:`

string_map_name- identifies the string map.

`Returns:` text_t

`*MARK_SAFE`

Mark the PIXL expression safe without applying any safe transform.

`Returns:` text_t

`*MAX` (text_t s)

Compares the string argument with the current string and returns the max string. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*MIN` (text_t s)

Compares the string argument with the current string and returns the min string. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*NE` (text_t s)

Results in Boolean TRUE value if the Text object is not equal to the input argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*NORMALIZE_URL`

Normalize URL. Normalizes a URL by doing "percent" decoding. See the description for URLENCODED in the SET_TEXT_MODE function. This performs the equivalent of SET_TEXT_MODE(URLENCODED).DECODE_USING_TEXT_MODE, except that it does not change the value of the current text mode.

`Returns:` text_t

`*PKEY_ENCRYPT_PEM_NO_PADDING` (text_t pem_pkey)

Encrypts the input text using the RSA public key provided by the PEM string and RSA_NO_PADDING padding method. The input text to be encrypted cannot be longer than the public key length minus 11 bytes for padding. For example, for a 1024-bit (128 byte) key, the input text cannot be longer than 128 - 11 = 117 bytes. An Undef error will occur if the input text is too long. A null input will also cause an Undef error. Returns the (unencoded binary) encrypted text, which is typically base-64 encoded for use in a message.

`Parameters``:`

pem_pkey- a text expression that supplies a RSA public key in the PEM format. If the text value is not a valid PEM RSA PUBLIC KEY encoding, an Undef error will occur. Example (a 1024-bit public key):

```
"-----BEGIN RSA PUBLIC KEY-----" +

"MIGJAoGBAKl5vgQEj73Kxp+9yn1v5gPR1pnc4oLM2a0kaWwBOsB6rzCIy6znwnvw" +

"CY1xRvQhRlJSAyJbloL7wZFIJ2FOR8Cz+8ZQWXU2syG+udi4EnWqLgFYowF9zK+o" +

"79az597eNPAjsHZ/C2oL/+6qY5a/f1z8bQPrHC4GpFfAEJhh/+NnAgMBAAE=" +

"-----END RSA PUBLIC KEY-----"
```

`Returns:` text_t

`*PKEY_ENCRYPT_PEM` (text_t pem_pkey)

Encrypts the input text using the RSA public key provided by the PEM string and the RSA_PKCS1_PADDING padding method. The input text to be encrypted cannot be longer than the public key length minus 11 bytes for padding. For example, for a 1024-bit (128 byte) key, the input text cannot be longer than 128 - 11 = 117 bytes. An Undef error will occur if the input text is too long. A null input will also cause an Undef error. Returns the (unencoded binary) encrypted text, which is typically base-64 encoded for use in a message.

`Parameters``:`

pem_pkey- a text expression that supplies a RSA public key in the PEM format. If the text value is not a valid PEM RSA PUBLIC KEY encoding, an Undef error will occur. Example (a 1024-bit public key):

```
"-----BEGIN RSA PUBLIC KEY-----" +

"MIGJAoGBAKl5vgQEj73Kxp+9yn1v5gPR1pnc4oLM2a0kaWwBOsB6rzCIy6znwnvw" +

"CY1xRvQhRlJSAyJbloL7wZFIJ2FOR8Cz+8ZQWXU2syG+udi4EnWqLgFYowF9zK+o" +

"79az597eNPAjsHZ/C2oL/+6qY5a/f1z8bQPrHC4GpFfAEJhh/+NnAgMBAAE=" +

"-----END RSA PUBLIC KEY-----"
```

`Returns:` text_t

`*PKEY_SIGN_CERTKEY` (text_t certkey_name)

Generates a binary digital signature using the SHA-256 message digest function and an RSA private key from the specified SSL certKey object.

`Parameters``:`

certkey_name- identifies the configured certKey object. Results in an Undef error if the certkey object does not exist or does not contain an RSA private key, or if the signing operation cannot complete.

`Returns:` text_t

`*PKEY_SIGN_XML` (text_t xml_pkey)

Generates a binary digital signature using the SHA-256 message digest function and an RSA private key from the specified XML element.

`Parameters``:`

xml_pkey- an expression that supplies an <RSAKeyValue> element with the private key. Example: <RSAKeyValue> <Modulus>qXm+BASPvcrGn73KfW/mA9HWmdzigszZrSRpbAE6wHqvMIjLrOfCe/AJjXFG9CFGUlIDIluWgvvBkUgnYU5HwLP7xlBZdTazIb652LgSdaouAVijAX3Mr6jv1rPn3t408COwdn8Lagv/7qpjlr9/XPxtA+scLgakV8AQmGH/42c=</Modulus> <Exponent>AQAB</Exponent>"zNjysxcIJV/J9cTpIgPp2/x1IXHT5GTH8OMuNad0qtRSLjU1QYUmmkm9QcJJAN+7h8FEXWGabySUzBrHj/IEbw==" <DP>QavUDQLLQpnPJXtVAo6CYhxOMCd68mwTxYKKNLjmC0pd54SFHllTLPE1FZU5EjK6q3nCeijonpfH+XXDP> <DQ>EiXOKouJzzXTQJC3TqomF7Uf81yQNxWumOqnd11kepXgyfMwyqMvLlAGEkNSEF/Bz18R3Wv+MIZ/IC3nLBt2xQ==</DQ> <InverseQ>ocuCmz36CP+N2aGqxaU+BKD5+3RLgRq9LFhULEz2jKx0iV9r76jsAxn3sLcTYYO9eqRPy2cz74AUnw==</InverseQ> <D>fTBD773a3GzcmgVdfZlaBLpN1ux2mf5uUVrTUQf7eVFm9egm4/tzC5A9zjC+I/oscwTH8epL3UfRLdtp05Q6pWfJBXEnGo0QmOFFBK4pLx/5JJpPGZ69ovDFEVOUHyiCfKE/g97T4WX3us0nFe1272zwGlHarM1YYwvfeE08UdE=</D> </RSAKeyValue> Results in an Undef error if the XML element is invalid or does not correctly specify an RSA private key, or if the signing operation cannot complete.

`Returns:` text_t

`*PKEY_VERIFY_CERTKEY` (text_t certkey_name, text_t signature)

Verifies if the input text matches the specified signature generated using the SHA-256 messge digest function and the RSA private key associated with the specified RSA public key in the X.509 certificate in the specified certKey object. Returns true if the signature is verified, false otherwise.

`Parameters``:`

certkey_name- identifies the certkey object containing an X.509 certificate holding the RSA public key.

signature- the binary signature. Results in an Undef error if the certkey object does not exist or does not contain an X.509 certificate with an RSA public key, or if the verification operation cannot complete.

`Returns:` bool_at

`*PKEY_VERIFY_XML` (text_t xml_pkey, text_t signature)

Verifies if the input text matches the specified signature generated using the SHA-256 messge digest function and the RSA private key associated with the RSA public key supplied by the specified XML element. Returns true if the signature is verified, false otherwise.

`Parameters``:`

xml_pkey- an expression that supplies an <RSAKeyVAlue> element with the public key. Example: <RSAKeyValue> <Modulus>qXm+BASPvcrGn73KfW/ mA9HWmdzigszZrSRpbAE6wHqvMIjLrOfCe/ AJjXFG9CFGUlIDIluWgvvBkUgnYU5HwLP7xlBZdTazIb652LgSdaouAVijAX3Mr6jv1rPn3t408COwdn8Lagv/ 7qpjlr9/XPxtA+scLgakV8AQmGH/42c=</Modulus> <Exponent>AQAB</Exponent> </ RSAKeyValue>

signature- the binary signature. Results in an Undef error if the XML element is invalid or does not correctly specify an RSA public key, or if the verification operation cannot complete.

`Returns:` bool_at

`*PREFIX` (`char` c, `uint` i)

Select a prefix of the Text. The selected prefix is the longest prefix that has at most Count (2nd argument) occurrences of character in the 1st argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

c- Character

i- Count

`Returns:` text_t

`*PREFIX` (`uint` i)

Select a prefix of the Text. The length of the prefix is equal to the number in the argument. If there aren't enough characters in the Text object then the entire Text is selected.

`Parameters``:`

i- Prefix Length

`Returns:` text_t

`*REGEX_MATCH` (`re` regex)

Returns TRUE if and only if the text contains at least one match of the regular expression argument. The match may occur anywhere within the text - if you wish to "anchor" this, use "\^" at the start of the regex and/or "$" at the end of the regex.

The regular expression has to be of the format: `re<delimiter>regular expression<same delimiter>`

The regular expression cannot be bigger than 1499 characters.

The regular expression should be acceptable by the PCRE regular expression library. Look at http://www.pcre.org/pcre.txt for documentation on the regular expression syntax. In particular, look at the pcrepattern man page.

There are some differences in the allowed syntax w.r.t PCRE syntax. Backreferences are not allowed. It is recommended not to use recursive regular expressions. The dot metacharacter matches newlines also. Unicode is not supported. SET_TEXT_MODE(IGNORECASE) overrides the (?i) internal option specified in the regular expression.

The PCRE library configuration can be seen in the system log, after executing 'nsapimgr -B" call ns_pixl_regex_show_config()"' at the shell prompt.

Some examples:

- HTTP.REQ.HOSTNAME.REGEX_MATCH(re/\[\[:alpha:\]\]+(abc){2,3}/)
- HTTP.REQ.URL.SET_TEXT_MODE(URLENCODED).REGEX_MATCH(re#(a*b+c*)#)
- HTTP.REQ.URL.REGEX_MATCH(re/a(?i)b/) matches ab and aB
- HTTP.REQ.URL.SET_TEXT_MODE(IGNORECASE).REGEX_MATCH(re/ab/) matches ab, aB, Ab and AB
- HTTP.REQ.BODY.REGEX_MATCH(re/(?ixm) (\^ab (.*) cd$) /) does a case-insensitive, multiline match where the dot metacharacter matches newline also. The regex itself can contain whitespace which will be ignored during the matching (x - extended regex).

This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

regex- Regular Expression

`Returns:` bool_at

`*REGEX_REPLACE` (`re` regex, text_t replacement, replacemode_e mode)

Selects the text that matches the given regular expression argument and replaces it with the the text given in the second argument. The third argument specifies whether the first match is only replaced when multiple matches occur in the text or all matches are replaced. The match may occur anywhere within the text - if you wish to "anchor" this, use "\^" at the start of the regex and/or "$" at the end of the regex. When the regular expression does not match the given string then the same string is returned.

For example: HTTP.RES.BODY(999).REGEX_REPLACE(re!\\bpassword:\\s*\\b!, "password: ***", ALL) will replace all occurrences of "password:" with "password: ***" This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

regex- Regular Expression

replacement- String to replace the match

mode- Mode of replacement

`Returns:` text_t

`*REGEX_SELECT` (`re` regex)

Selects the text that matches the given regular expression argument. The first match is returned when multiple matches occur in the text. The match may occur anywhere within the text - if you wish to "anchor" this, use "\^" at the start of the regex and/or "$" at the end of the regex. When the regular expression does not match the given string, a Text object of length of 0 is returned.

For example: HTTP.REQ.HEADER("via").REGEX_SELECT(re!NS-CACHE-\\d\\.\\d:\\s*\\d{1,3}!) will select "NS-CACHE-7.0: 70" This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

regex- Regular Expression

`Returns:` text_t

`*REPEAT` (`uint` i)

Produces a string which contains 'i' sequential copies of the input string.

`Parameters``:`

i- the number of times to repeat the string (0 or more)

`Returns:` text_t

`*SET_CHAR_SET` (charset_e charset)

Set the character set to use for subsequent functions that use text.

`Parameters` (expressions not allowed)`:`

charset- Character Set

`Returns:` dns_domainname_t

`*SET_TEXT_MODE` (textmode_e mode)

The mode setting of a Text object controls the behavior of many Text operations. The Text mode settings may also control the behavior of some operations in objects (like List) that build upon the Text object. IGNORECASE, NOIGNORECASE - controls whether string comparison is case sensitive or not. URLENCODED - If set then all Text operations are carried out after translating all %HH or %uHHHH encodings in the underlying byte stream. 1. %HH will be translated to the character Y where HH denotes the ascii value of character Y in hexadecimal. For example, the encoded text "http%3a/.html" will be decoded to "http:/.html" 2. %uWWHH will be translated to the character sequence YZ where WW denotes the ascii value of character Y in hexadecimal and HH denotes the ascii value of character Z in hexadecimal. For example, the encoded text "http%u3a2f.html" and "http%u003a/.html" will both be decoded to"http:/.html" NOURLENCODED - Indicates that no percent encodings are present in the Text object. No percent decoding will be performed on the Text object. PLUS_AS_SPACE - If set then all Text operations are carried out after converting occurrences of the plus character to whitespace. For example, the text "hello+world" will be decoded to "hello world" NO_PLUS_AS_SPACE - If set, then the plus character will not be converted to whitespace in the Text object. BACKSLASH_ENCODED - If set, then all Text operations are carried out after performing the following operations: 1. \\XXX will be translated to the character Y where XXX denotes the ascii value of character Y in octal. The valid range of octal values for this type of encoding is \\0 to \\377. For example, the encoded text "http\ \72/.html" and "http\\072/.html" will both be decoded to "http:/.html" 2. \\xHH will be translated to the character Y where HH denotes the ascii value of character Y in hexadecimal. For example, the encoded text "http\\x3a/.html" will be decoded to "http:/.html" 3. \\\\uWWXX will be translated to the character sequence YZ where WW denotes the ascii value of character Y in hexadecimal and XX denotes the ascii value of character Z in hexadecimal. For example, the encoded text

"http%u3a2f.html" and "http%u003a/.html" will both be decoded to"http:/.html" 4. Occurences of "\ \b", "\\n", "\\t", "\\f" and "\\r" are translated to the corresponding ascii characters. NO_BACKSLASH_ENCODED - If set, then backslash decoding will not be performed on the Text object. BAD_ENCODE_RAISE_UNDEF - If set, then UNDEF is raised if either the URLENCODED or BACKSLASH_ENCODED mode is set and a bad encoding corresponding to the specified encoding mode is encountered. NO_BAD_ENCODE_RAISE_UNDEF - If set, then UNDEF will not be raised when a bad encoding is encountered in the Text object. The Text operations operate on characters (as opposed to operating on bytes). By default a single byte represents a character using the ASCII encoding. But if URLENCODED mode is set then 3 bytes may represent a character. A PREFIX(3) operation will select the first 3 characters in the Text object. That means it may select up to 9 bytes for URLENCODED Text object. In the case of multibyte decodings as a result of %uXXXX or \\\\uXXXX, Text operations which attempt to treat the multiple decoded bytes as distinct characters are not allowed.

`Parameters` (expressions not allowed) `:`

mode- Text Mode

`Returns:` dns_domainname_t

`*SKIP` (`char` c, `uint` i)

Select the Text after skipping over a prefix of the current Text. The skipped over prefix is the longest prefix that has at most Count (2nd argument) occurrences of character in the 1st argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

c- Character

i- Count

`Returns:` text_t

`*SKIP` (`uint` i)

Select the Text after skipping over a prefix in the current Text. The length of the prefix is equal to the number in the argument. If there aren't enough characters in the Text object then the entire Text is skipped over.

`Parameters` (expressions not allowed) `:`

i- Prefix Length

`Returns:` text_t

`*STARTSWITH_ANY` (text_t patset_name)

Results in Boolean TRUE value if the Text starts with any of the strings that are bound to the patset or dataset named by the string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` bool_at

`*STARTSWITH_INDEX` (text_t patset_name)

Returns the numerical index of the matching string, if the Text starts with any of the strings that are bound to the patset or dataset named by the string argument. Returns 0 if there is no match. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` num_at

`*STARTSWITH` (text_t start)

Results in Boolean TRUE value if a prefix of the Text object matches the string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

start- String

`Returns:` bool_at

`*STRIP_CHARS` (text_t s)

From the selected text remove the characters specified in the string.

For example: Say the selected text is / "foo.xyz=bar" /. Then on executing STRIP_CHARS('.=') or STRIP_CHARS('..=') the selected text will become /fooxyzbar /. Note that repeating character has

same effect as it would be if it present only once. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*STRIP_END_CHARS` (text_t s)

Selects the Text after stripping off characters in the end of the current Text object.

For example: Say the selected text is / "foo.xyz=bar" /. Then on executing STRIP_END_CHARS('ar') the selected text will become /foo.xyz=b /. Note that repeating character has same effect as it would be if it present only once. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*STRIP_END_WS`

Selects the Text after stripping off white space in the end of the current Text object.

`Returns:` text_t

`*STRIP_START_CHARS` (text_t s)

Selects the Text after stripping off characters in the beginning of the current Text object.

For example: Say the selected text is / "foo.xyz=bar" /. Then on executing STRIP_START_CHARS('of') the selected text will become /.xyz=bar /. Note that repeating character has same effect as it would be if it present only once. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*STRIP_START_WS`

Selects the Text after stripping off white space in the beginning of the current Text object.

`Returns:` text_t

`*SUBSTR_ANY` (text_t patset_name)

Select any one sub-string that matches any string in the given patset or dataset. The patset cannot have strings longer than 255 characters. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` text_t

`*SUBSTR` (`uint` start, `uint` len)

Select the Text object of the given length at the given offset. Offset it 0 based. If there aren't enough characters after the offset then all the remaining characters are selected.

`Parameters``:`

start- Offset

len- Length

`Returns:` text_t

`*SUBSTR` (text_t s)

Select the first Text object that matches the input string argument. The input string cannot be bigger than 255 characters. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*SUFFIX` (`char` c, `uint` i)

Select a suffix of the Text. The selected suffix is the longest possible suffix containing at most Count (2nd arg) occurrences of the character in the 1st argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

c- Character

i- Count

`Returns:` text_t

`*SUFFIX` (`uint` i)

Select a suffix of the Text. The length of the suffix is equal to the number in the argument. If there aren't enough characters in the Text object then the entire Text is selected.

`Parameters``:`

i- Suffix Length

`Returns:` text_t

`*TO_LOWER`

Converts the selected text to lower case.

For example, the string "ABCd" is converted to "abcd"

`Returns:` text_t

`*TO_UPPER`

Converts the selected text to upper case.

For example, the string "abcD" is converted to "ABCD"

`Returns:` text_t

`*TRUNCATE` (`char` c, `uint` i)

Select the Text after truncating a suffix from the current Text object. The truncated suffix is the longest possible suffix containing at most Count (2nd arg) occurrences of the character in the 1st argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

c- Character

i- Count

`Returns:` text_t

`*TRUNCATE` (`uint` i)

Select the Text after truncating a suffix of the Text. The length of the suffix truncated is equal to the number in the argument. If there aren't enough characters in the Text then then all the characters are truncated.

`Parameters``:`

i- Suffix Length

`Returns:` text_t

`*TYPECAST_AVP_T`

Convert text_t to avp_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (avp_t : Operations that can be performed on the returned AVPs.

`Note:` An AVP can have multiple instances in a Diameter message. However, the system can access only the first 16 instances.

`Example:`

- To get the first value of AVP code 266 from a request, use: DIAMETER.REQ.AVP(266).VALUE(0).
- To get the fourth value of AVP code 266 from a request, use: DIAMETER.REQ.AVP(266).VALUE(3).
- To check if AVP code 1000 in the response has the vendor-specific bit set, use: DIAMETER.RES.AVP(1000).IS_VENDOR_SPECIFIC.

)

`Returns:` avp_t

`*TYPECAST_AVP_UNUM_T`

Convert text_t to avp_unum_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (avp_unum_t : In Diameter AVP based expressions can be written as DIAMETER.REQ.AVP(<avpcode>). For example Auth-Application-Id AVP (AVP code

258) can be extracted as DIAMETER.REQ.AVP(258) For few of the important AVPs we provide aliases. For example this AVP based expression can also be written as DIAMETER.REQ.AUTH_APPLICATION_ID. This expression returns either a object of class avp_t or returns a numerical value (object of class unsigned_long_at). The numerical value for this object is derived from the value in first instance of the AVP.)

`Returns:` avp_unum_t

`*TYPECAST_BOOL_AT`

Convert text_t to bool_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (bool_at : Boolean Operations)

`Returns:` bool_at

`*TYPECAST_COOKIE_T`

Convert text_t to cookie_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (cookie_t : The HTTP Cookie type provides operations for a cookie as it appears in the Set-Cookie and Set-Cookie2 header. In this type the Name-Value List operations are also available. The first delimiter is = and the element delimiter is ;. Multiple consecutive ; are treated as one. (Same as applying the method IGNORE_EMPTY_ELEMENTS on a Name-Value List.) You can use the Name-value List operations to access cookie attributes. The name comparison for all list operations is case insensitive. In this type Text operations are also available. Each cookie begins with a COOKIE_NAME=COOKIE_VALUE pair followed by zero or more semi-colon separated attribute-value pairs. If an attribute appears more than once in a cookie, the value associated with the first appearance of the attribute is returned.

Format Cookie: Cookie1=Value;Version=decimal;Value;Domain=Value;Path=Value)

`Returns:` cookie_t

`*TYPECAST_DIAMETER_FLAG_T`

Convert text_t to diameter_flag_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (diameter_flag_t : Provides operation to treat the underlying 1 byte as set of bit flags. then set/unset/test/reset_all operations can be done on flag)

`Returns:` diameter_flag_t

`*TYPECAST_DNS_DOMAINNAME_T`

Convert text_t to dns_domainname_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (dns_domainname_t : This object provides operations for parsing the DNS domain name as it appears at various places in the DNS data. The format is abc.foo.com.)

`Returns:` dns_domainname_t

`*TYPECAST_DNS_FLAG_T`

Convert text_t to dns_flag_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (dns_flag_t : Provides operations to test/set/unset a flag in dns header.)

`Returns:` dns_flag_t

`*TYPECAST_DOUBLE_AT`

Convert text_t to double_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_at : Double Value)

`Returns:` double_at

`*TYPECAST_DOUBLE_T` (double_format_e format)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error.)

`Parameters` (expressions not allowed) `:`

format- Format

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, double_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the

beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, ip_address_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, num_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, time_local_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, time_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, unsigned_long_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_HTTP_CACHE_CONTROL_T`

Convert text_t to http_cache_control_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_cache_control_t : This object provides for the ability to work on HTTP Cache-Control headers. The name comparison for all list operations is case insensitive.)

`Returns:` http_cache_control_t

`*TYPECAST_HTTP_CONTENT_LENGTH_T`

Convert text_t to http_content_length_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_content_length_t : The HTTP.REQ.CONTENT_LENGTH or HTTP.RES.CONTENT_LENGTH object can be treated as a HTTP Header or as a Number. The numerical value for this object is derived from the value in the last instance of the Content-Length header.)

`Returns:` http_content_length_t

`*TYPECAST_HTTP_COOKIE_T`

Convert text_t to http_cookie_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_cookie_t : This object provides operations for parsing the HTTP cookie header. The name-value pair is derived from the value in the last instance of Cookie header. The format is Cookie : name0=value0; name1=value1; An HTTP Cookie header can have multiple occurrences. COUNT will return a Number containing how many headers of the

current type exist. The name comparison for all list operations is case insensitive. The system does not keep track of more than 15 HTTP headers. The result will be undefined if there are more than 15 instances of the header.)

`Returns:` http_cookie_t

`*TYPECAST_HTTP_DATE_T`

Convert text_t to http_date_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_date_t : The HTTP.REQ.DATE or HTTP.RES.DATE object can be treated as a HTTP header or a Time object. The Time value is derived from the value in the last instance of the Date header. The date formats supported are RFC 822 (updated by RFC 1123), RFC 1036 (obsoletes RFC850) and ANSI C asctime() formats.)

`Returns:` http_date_t

`*TYPECAST_HTTP_HEADER_T` (text_t name)

Convert text_t to http_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_header_t : When typecasting a Text object to HTTP Header a header name must be provided.For example: HTTP.REQ.HEADER("MyHdr").TYPECAST_HTTP_HEADER_T("InHdr"))

`Parameters` (expressions not allowed) `:`

name- Header Name

`Returns:` http_header_t

`*TYPECAST_HTTP_HOSTNAME_T`

Convert text_t to http_hostname_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_hostname_t : This object provides operations for parsing the HTTP hostname as it appears at various places in the HTTP protocol data. The format is abc.foo.com:8080.)

`Returns:` http_hostname_t

`*TYPECAST_HTTP_METHOD_T`

Convert text_t to http_method_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_method_t : This object provides Text operations and HTTP Request Method Enum operations on the HTTP request method.)

`Returns:` http_method_t

`*TYPECAST_HTTP_SET_COOKIE_T`

Convert text_t to http_set_cookie_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_set_cookie_t : HTTP.RES.SET_COOKIE provides operations for parsing and operating on the SET-COOKIE header that is present in the HTTP response. HTTP Set-Cookie header supports Text and HTTP Header operations. For most Text operations the value in the last Set-Cookie header is selected. HTTP Set-Cookie header also supports special operations to extract cookies from the response. It is assumed that there will be only one cookie in a Set-Cookie header.)

`Returns:` http_set_cookie_t

`*TYPECAST_HTTP_URL_T`

Convert text_t to http_url_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_url_t : HTTP.REQ.URL provides operations for parsing and operating on the URL that is present in the first line of the HTTP request header. The supported format is \[<protocol>://<hostname>\]<path>?<query>. The Text object backing a HTTP URL object has the Text Mode set to URLENCODED by default.)

`Returns:` http_url_t

`*TYPECAST_HTTP_VERSION_T`

Convert text_t to http_version_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_version_t : HTTP.REQ.VERSION or HTTP.RES.VERSION provide operations to extract HTTP version information.)

`Returns:` http_version_t

`*TYPECAST_IPV6_ADDRESS_AT`

Convert text_t to ipv6_address_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ipv6_address_at : Provides operations for the 128-bit IPv6 address value. Some general information regarding IPv6 expressions: IPv6 PIXL expressions can be combined with other PIXL expressions using the '+' operator. The output is expected to be the concatenation of the string representations of the individual PIXL expressions. No other operator other than '+' is expected to work when any of the operands is an IPv6 PIXL expression. Also, IPv6 PIXL expressions can be combined with any other type of PIXL expression except a PIXL expression that produces a bool result. In other words, if A and/or B are two IPv6 addresses,

A+B should result in the string AB. When one of A or B is an IPv6 address, the other can only be a number or a string and not a boolean. Further, when A and/or B is an IPv6 address, the only operator allowed between them is '+'.

Example: Let the client source IPv6 address be ABCD:1234::ABCD. Let the server destination IPv4 address be 10.100.10.100. Then the expression CLIENT.IPV6.SRC + SERVER.IP.DST should produce the output "ABCD:1234::ABCD10.100.10.100". Similarly, CLIENT.IPV6.SRC + 5 should produce the result ABCD:1234::ABCD5)

`Returns:` ipv6_address_at

`*TYPECAST_IPV6_ADDRESS_T`

Convert text_t to ipv6_address_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ipv6_address_t : This object represents an IPv6 address present in the 1000:1001:CD10:0000:0000:89AB:4567:CDEF format.)

`Returns:` ipv6_address_t

`*TYPECAST_IPV6_SUBNET_AT`

Convert text_t to ipv6_subnet_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ipv6_subnet_at : Provides operations for the integral IPv6 subnet address value.)

`Returns:` ipv6_subnet_at

`*TYPECAST_IPV6_SUBNET_T`

Convert text_t to ipv6_subnet_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ipv6_subnet_t : This object represents an IPv6 subnet address present in the 1000:1001:CD10:0000:0000:89AB:4567:CDEF/64 format.)

`Returns:` ipv6_subnet_t

`*TYPECAST_IP_ADDRESS_AT`

Convert text_t to ip_address_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ip_address_at : Provides operations for the 32-bit integral IP address value.)

`Returns:` ip_address_at

`*TYPECAST_IP_ADDRESS_T`

Convert text_t to ip_address_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ip_address_t : Represents an IP address present in the 10.100.200.1 format.)

`Returns:` ip_address_t

`*TYPECAST_IP_OPTIONS_T`

Convert text_t to ip_options_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ip_options_t : IP protocol options)

`Returns:` ip_options_t

`*TYPECAST_IP_OPTIONS_TYPE_T`

Convert text_t to ip_options_type_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ip_options_type_t : IP Options Type)

`Returns:` ip_options_type_t

`*TYPECAST_IP_TOS_T`

Convert text_t to ip_tos_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ip_tos_t : Provides operations to TOS field in IP header.)

`Returns:` ip_tos_t

`*TYPECAST_LIST_T` (`char` sep)

Convert text_t to list_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (list_t : The character separator has to be provided when typecasting a textual context to list type. The current text mode has no effect on the character separator. For example if the current text mode is IGNORECASE and the separator is p then P will not be treated as a separator.)

`Parameters` (expressions not allowed) `:`

sep- Separator

`Returns:` list_t

`*TYPECAST_MAC_ADDRESS_AT`

Convert text_t to mac_address_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (mac_address_at : Provides operations for the 48-bit MAC address value.)

`Returns:` mac_address_at

`*TYPECAST_MAC_ADDRESS_T`

Convert text_t to mac_address_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (mac_address_t : Represents a MAC address present in the 12:34:56:78:9a:bc format.)

`Returns:` mac_address_t

`*TYPECAST_NUM_AT`

Convert text_t to num_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (num_at : Number Value)

`Returns:` num_at

`*TYPECAST_NUM_T` (num_format_e format)

Convert text_t to num_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (num_t : Treat the underlying text as a Number in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error.)

`Parameters` (expressions not allowed) `:`

format- Format

`Returns:` num_t

`*TYPECAST_NUM_T` (num_format_e format, num_at default_value)

Convert text_t to num_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (num_t : Treat the underlying text as a Number in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL

and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` num_t

`*TYPECAST_NVLIST_T` (`char` sep1, `char` sep2)

Convert text_t to nvlist_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (nvlist_t : Two character delimiters have to be provided when typecasting a Text object to a Name-Value List. The first delimited separates the name from the value. The second delimiter separates list items. For example typecast_nvlist_t('=', '&') handles a URL query string. The Text Mode has no effect on the character delimiters. For example if the current text mode is IGNORECASE and a delimiter is p then P will not be treated as a delimiter.)

`Parameters` (expressions not allowed) `:`

sep1- delimiter1

sep2- delimiter2

`Returns:` nvlist_t

`*TYPECAST_NVLIST_T` (`char` sep1, `char` sep2, `char` quote)

Convert text_t to nvlist_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (nvlist_t : Two character delimiters and quote-character have to be provided when typecasting a Text object to a Name-Value List that supports quote-character. The first delimited separates the name from the value. The second delimiter separates list items. The third value specifies the quote character. For example typecast_nvlist_t('=', ';', "") handles a name-value list separated by semi-colons that allows quoting. The quote-character specifies that the value can occur within the quotes and the delimiters within the quote-characters should not be taken into account. The Text Mode has no effect on the character delimiters. For example if the current text mode is IGNORECASE and a delimiter is p then P will not be treated as a delimiter.)

`Parameters` (expressions not allowed) `:`

sep1- delimiter1

sep2- delimiter2

quote- quote-character.

`Returns:` nvlist_t

`*TYPECAST_PROTOCOL_BUFFER_T`

Convert text_t to protocol_buffer_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (protocol_buffer_t : gRPC Protocol Buffers interface)

`Returns:` protocol_buffer_t

`*TYPECAST_RADIUS_AVP_T`

Convert text_t to radius_avp_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (radius_avp_t : Operations that can be performed on the returned AVPs.

`Note:` An AVP can have multiple instances in a radius message. However, the system can access only the first 16 instances.

`Example:`

- To get the first value of AVP code 26 from a request, use: radius.REQ.AVP(26).VALUE(0).
- To get the fourth value of AVP code 26 from a request, use: radius.REQ.AVP(26).VALUE(3).

)

`Returns:` radius_avp_t

`*TYPECAST_RADIUS_AVP_VALUE_T`

Convert text_t to radius_avp_value_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (radius_avp_value_t : Provides operations to typecast RADIUS AVP value to Integer value or IP Address.)

`Returns:` radius_avp_value_t

`*TYPECAST_SEQ_TEXT_T`

Convert text_t to seq_text_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (seq_text_t : Represents the Text Sequence class.)

`Returns:` seq_text_t

`*TYPECAST_SERVICEPATH_T`

Convert text_t to servicepath_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (servicepath_t : Operations that can be performed on the service path.

`Example:`

- To get the name of the service path applicable to current subscriber, use: SUBSCRIBER.SERVICEPATH
- To determine If the service function is the next in the service path applicable to scubscriber, use: SUBSCRIBER.SERVICEPATH.IS_NEXT().

)

`Returns:` servicepath_t

`*TYPECAST_SIP_CALLID_HEADER_T`

Convert text_t to sip_callid_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_callid_header_t : This object provides operations for parsing the SIP callid header.)

`Returns:` sip_callid_header_t

`*TYPECAST_SIP_CONTENT_LENGTH_T`

Convert text_t to sip_content_length_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_content_length_t : The SIP.REQ.CONTENT_LENGTH or SIP.RES.CONTENT_LENGTH object can be treated as a SIP Header or as a Number. The numerical value for this object is derived from the value in the last instance of the Content-Length header.)

`Returns:` sip_content_length_t

`*TYPECAST_SIP_FROM_HEADER_T`

Convert text_t to sip_from_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_from_header_t : This object provides operations for parsing the SIP From header.)

`Returns:` sip_from_header_t

`*TYPECAST_SIP_HEADER_T` (text_t name)

Convert text_t to sip_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_header_t : When typecasting a Text object to SIP Header a header name must be provided.For example: SIP.REQ.HEADER("MyHdr").TYPECAST_SIP_HEADER_T("InHdr"))

`Parameters` (expressions not allowed) `:`

name- Header Name

`Returns:` sip_header_t

`*TYPECAST_SIP_HOSTNAME_T`

Convert text_t to sip_hostname_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_hostname_t : This object provides operations for parsing the SIP hostname as it appears at various places in the SIP protocol data. The format is abc.foo.com:5060.)

`Returns:` sip_hostname_t

`*TYPECAST_SIP_METHOD_T`

Convert text_t to sip_method_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_method_t : This object provides Text operations and SIP Request Method Enum operations on the SIP request method.)

`Returns:` sip_method_t

`*TYPECAST_SIP_TO_HEADER_T`

Convert text_t to sip_to_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_to_header_t : This object provides operations for parsing the SIP From header.)

`Returns:` sip_to_header_t

`*TYPECAST_SIP_URL_T`

Convert text_t to sip_url_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_url_t : SIP.REQ.URL provides operations for parsing and operating on the URL that is present in the first line of the SIP request header. The supported format is \[<protocol>://<hostname>\]<path>?<query>. The Text object backing a SIP URL object has the Text Mode set to URLENCODED by default.)

`Returns:` sip_url_t

`*TYPECAST_SIP_VERSION_T`

Convert text_t to sip_version_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_version_t : SIP.REQ.VERSION or SIP.RES.VERSION provide operations to extract SIP version information.)

`Returns:` sip_version_t

`*TYPECAST_SIP_VIA_HEADER_T`

Convert text_t to sip_via_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_via_header_t : This object provides operations for parsing the SIP Via header.)

`Returns:` sip_via_header_t

`*TYPECAST_SSLVPN_MODE_T`

Convert text_t to sslvpn_mode_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sslvpn_mode_t : This object provides Text operations and SSLVPN Mode Enum operations on the SSLVPN request method.)

`Returns:` sslvpn_mode_t

`*TYPECAST_SSL_TEXT_T` (text_t name)

Convert text_t to ssl_text_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ssl_text_t : Treat the underlying text object as SSL Text.)

`Parameters` (expressions not allowed) `:`

name- Name

`Returns:` ssl_text_t

`*TYPECAST_TCP_OPTIONS_T`

Convert text_t to tcp_options_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (tcp_options_t : TCP Protocol Options)

`Returns:` tcp_options_t

`*TYPECAST_TCP_OPTIONS_TYPE_T`

Convert text_t to tcp_options_type_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (tcp_options_type_t : TCP Protocol Options Type)

`Returns:` tcp_options_type_t

`*TYPECAST_TCP_REPEATER_OPTION_T`

Convert text_t to tcp_repeater_option_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (tcp_repeater_option_t : TCP Protocol Option : Repeater)

`Returns:` tcp_repeater_option_t

`*TYPECAST_TIME_AT`

Convert text_t to time_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (time_at : Treats a number value as number of seconds since GMT Jan 1 1970 0h 0m 0s.)

`Returns:` time_at

`*TYPECAST_TIME_LOCAL_AT`

Convert text_t to time_local_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (time_local_at : Treats a number value as number of seconds since GMT Jan 1 1970 0h 0m 0s as adjsuted for the local time zone.)

`Returns:` time_local_at

`*TYPECAST_TIME_T`

Convert text_t to time_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (time_t : This object treats a Text object as a date string. The formats supported are

1\. RFC822 :: Sun, 06 Nov 1994 08:49:37 GMT 2\. RFC850 :: Sunday, 06-Nov-94 08:49:37 GMT 3\. ASCTIME :: Sun Nov 6 08:49:37 1994 4\. ASCTIME like :: Sun Nov 6 08:49:37 1994 5\. ASCTIME like :: Sun Nov 06 08:49:37 1994 6\. Http Set-Cookie Expiry date :: Sun, 06-Nov-1994 08:49:37 GMT)

`Returns:` time_t

`*TYPECAST_UNSIGNED_LONG_AT`

Convert text_t to unsigned_long_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_at : Unsigned Long(64bit) Value)

`Returns:` unsigned_long_at

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error.)

`Parameters` (expressions not allowed) `:`

format- Format

`Returns:` unsigned_long_t

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format, ip_address_at default_value)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` unsigned_long_t

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format, unsigned_long_at default_value)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` unsigned_long_t

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format, num_at default_value)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` unsigned_long_t

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format, time_local_at default_value)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` unsigned_long_t

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format, time_at default_value)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` unsigned_long_t

`*TYPECAST_UNUM_TEXT_T`

Convert text_t to unum_text_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unum_text_t : Provides operations to treat the underlying OctectString as Binary String or unsigned long value .)

`Returns:` unum_text_t

`*TYPECAST_URL_CATEGORY_T`

Convert text_t to url_category_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (url_category_t : Retrieves URL category and attributes from an URL)

`Returns:` url_category_t

`*TYPECAST_VENDOR_SPEC_APPID_AVP_T`

Convert text_t to vendor_spec_appid_avp_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (vendor_spec_appid_avp_t : Retrieves AVPs that are nested in the grouped AVP Vendor-Specific-Application-Id (code 260). The nested AVPs are:

- Vendor-Id
- Auth-Application-Id
- Acct-Application-Id

For example, to retrieve the Auth-Application-Id AVP from the Vendor-Specific-Application-Id AVP:

- For requests:
  DIAMETER.REQ.VENDOR_SPECIFIC_APPLICATION_ID.AUTH_APPLICATION_ID
- For responses:
  DIAMETER.RES.VENDOR_SPECIFIC_APPLICATION_ID.AUTH_APPLICATION_ID

)

`Returns:` vendor_spec_appid_avp_t

`*TYPECAST_VENDOR_SPEC_RADIUS_AVP_T`

Convert text_t to vendor_spec_radius_avp_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (vendor_spec_radius_avp_t :

- Vendor-Id

To retrieve the Vendor-Id from the Vendor-Specific AVP:

- RADIUS.REQ.VENDOR_SPECIFIC.VENDORID

)

`Returns:` vendor_spec_radius_avp_t

`*UNQUOTE` (`char` c)

If selected text is quoted by character c, Remove character c from beginning and end.

For example: Say the selected text is / "foo xyz bar " /. Then on executing UNQUOTE("") the selected text will become /foo xyz bar / This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

c- Character

`Returns:` text_t

`*URLSET_MATCHES_ANY` (text_t urlset_name)

Results in Boolean TRUE value if and only if the Text matches any of the patterns that are specified in the urlset named by the string argument. The matching is case-insensitive for domains, but case-sensitive for paths. For example:

- HTTP.REQ.HOST.APPEND(HTTP.REQ.URL).URLSET_MATCHES_ANY("urlset_forbidden") returns true when the combined domain and URL matches any pattern in the urlset whose name is "urlset_forbidden".

`Parameters` (expressions not allowed) `:`

urlset_name- urlset name

`Returns:` bool_at

`*URL_CATEGORIZE` (`uint` min_reputation, `uint` max_reputation)

Returns the URL category for the supplied URL with the given minimum and maximum reputation score. Where a score of 5 is most risky and 1 is least risky. If either score is set to 0, that bound would be ignored. By specifying the reputation scores, the function will returned the category with the highest score (most risky) based on the bounds. If there was an error getting the category or if the URL is invalid then it will result in an Undef error. For example:

HTTP.REQ.HOST.APPEND(HTTP.REQ.URL).URL_CATEGORIZE(0, 0) returns value when the combined domain and URL is looked up for the URL category with the highest reputation score (most risky).

`Parameters` (expressions not allowed) `:`

min_reputation- Minimum reputation score of URL category

max_reputation- Maximum reputation score of URL category

`Returns:` url_category_t

`*URL_RESERVED_CHARS_SAFE`

Converts URL reserved characters to corresponding '%XX' values and retains the rest. This is a read only operation.

```
Based on RFC3986, following are considered URL unreserved characters:

    Alpha-numeric characters: a-z, A-Z, 0-9

    Hyphen and underscore: "-", "_"

    Dot: "."

    Tilde: "~"
```

The rest are converted to %XX encoding, 'XX' is the hex-based representation of the input character. If the requirement is to encode all but URL safe characters, please consider using HTTP_URL_SAFE method.

`Returns:` text_t

`*XML_DECRYPT` (text_t certKeyName)

Decrypt the selected content, which was encrypted using the W3C XML Encryption standard.

`Parameters` (expressions not allowed) `:`

certKeyName- identifies the certkey object containing the RSA private key to be used to decrypt the bulk encryption key in the selected EncryptedData element.

`Returns:` text_t

`*XML_ENCRYPT` (text_t certKeyName, encrypt_method_e method)

Encrypt the selected cleartext using the W3C XML Encryption standard.

`Parameters` (expressions not allowed) `:`

certKeyName- identifies the certkey object containing an X.509 certificate with the RSA public key to be used to encrypt the generated bulk encryption key. Note that the certKey object need not, and usually will not, include the associated RSA private key.

method- specifies the bulk encryption method (rc4, des3, aes128, aes192, or aes256) used to encrypt the content.

`Returns:` text_t

`*XML_ENCRYPT` (text_t certKeyName, encrypt_method_e method, `uint` flags)

Encrypt the selected cleartext using the W3C XML Encryption standard.

`Parameters` (expressions not allowed) `:`

certKeyName- identifies the certkey object containing an X.509 certificate with the RSA public key to be used to encrypt the generated bulk encryption key. Note that the certKey object need not, and usually will not, include the associated RSA private key.

method- specifies the bulk encryption method (rc4, des3, aes128, aes192, or aes256) used to encrypt the content.

flags- optional bit mask to specify optional elements in the EncryptedData element. These are hints to tell the receiver what private key to use to decrypt the bulk encryption key, providing information from the certKey's X.509 certificate.

- 1 - include a KeyName element with the certKeyName;
- 2 - include a KeyValue element with the RSA public key from the certificate;
- 4 - include an X509IssuerSerial element with the certificate serial number and issuer DN;
- 8 - include an X509SubjectName element with the certificate subject DN;
- 16 - include an X509Certificate element with the entire certificate;

`Returns:` text_t

`*XPATH_HTML_WITH_MARKUP` (`xpath_str` xpathex)

Applies an XPath expression to the DOM for an HTML document and returns the selected node-set or string, including markup like element tags. node-sets are converted to strings using the standard XPath string conversion routine. The selected portion of the document can be used as the target for rewrite actions.

Examples: HTTP.REQ.BODY(1000).XPATH_HTML_WITH_MARKUP(xp%//md/head/title%) returns the <title> element in the document's <head> This can be used in a rewrite action to replace or delete the <title> element.

`Parameters` (expressions not allowed) `:`

xpathex- XPath Expression

`Returns:` text_t

`*XPATH_HTML` (`xpath_bool` xpathex)

Applies an XPath expression to the DOM for an HTML document and a boolean value.

Examples: HTTP.RES.BODY(1000).XPATH_HTML(xp%boolean(/md/head/meta)%) returns true if the <meta> element exists as a child of <head> element.

`Parameters` (expressions not allowed) `:`

xpathex- XPath Expression

`Returns:` bool_at

`*XPATH_HTML` (`xpath_double` xpathex)

Applies an XPath expression to the DOM for an HTML document and a double value.

Examples: HTTP.RES.BODY(1000).XPATH_HTML(xp%number(//video/@height)%) returns the numeric value of the height attribute of the first <video> element.

`Parameters` (expressions not allowed) `:`

xpathex- XPath Expression

`Returns:` double_at

`*XPATH_HTML` (`xpath_str` xpathex)

Applies an XPath expression to the DOM for an HTML document and returns the selected node-set or string. node-sets are converted to strings using the standard XPath string conversion routine.

Examples: HTTP.REQ.BODY(1000).XPATH_HTML(xp%//img/@src%) returns the string value of the src attribute of the first

DNS_ECS_T

This object provides operations for parsing the DNS ECS option.

This topic lists the expressions that are provided by this class.

- `IP`

  Returns the representative IPv4 address of the 'address' field in EDNS client subnet.

`Returns:` ip_address_at

- `IPV6`

  Returns the representative IPv6 address of the 'address' field in EDNS client subnet.

`Returns:` ipv6_address_at

- `IS_IPV4`

  Returns true if EDNS client subnet option contains an IPv4 address

`Returns:` bool_at

- `IS_IPV6`

  Returns true if EDNS client subnet option contains an IPv6 address

`Returns:` bool_at

DNS_FLAG_E

This object represents one of the DNS header flags.

Enumerations

QR

AA

TC

RD

RA

RESERVED

AD

CD

DNS_FLAG_T

Provides operations to test/set/unset a flag in dns header.

This topic lists the expressions that are provided by this class.

`*Note` *: Expressions with the * symbol are inherited / promoted from text_t

- `GET_STRING_REPRESENTATION`

  Return all the flag bits set in the DNS header in string format

`Returns:` text_t

`*IS_SET` (dns_flag_e flag)

Test a flag bit in dns header.

`Parameters` (expressions not allowed) `:`

flag- bit

`Returns:` bool_at

`*SET` (dns_flag_e flag)

Set a flag bit in the DNS header. Returns dns_flag_t

`Parameters` (expressions not allowed) `:`

flag- bit

`Returns:` dns_flag_t

`*TYPECAST_TEXT_T`

Convert dns_flag_t to text_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (text_t : Designates any piece of text.)

`Returns:` text_t

`*UNSET` (dns_flag_e flag)

Unset a flag bit in the DNS header. Returns dns_flag_t

`Parameters` (expressions not allowed) `:`

flag- bit

`Returns:` dns_flag_t

`*AFTER_REGEX` (`re` regex)

Selects the text after the portion that matches the given regular expression argument. The first match is returned when multiple matches occur in the text. The match may occur anywhere within the text - if you wish to "anchor" this, use "\^" at the start of the regex and/or "$" at the end of the regex. When the regular expression does not match the given string, a Text object of length of 0 is returned.

Example: HTTP.REQ.HEADER("etag").AFTER_REGEX(re/KX/) will select "DAPPER" from "KXDAPPER". This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

regex- Regular Expression

`Returns:` text_t

`*AFTER_STR_ANY` (text_t patset_name)

Selects the Text that is present after the first occurrence of any of the strings that are bound to the patset named by the string argument. If there is no match to any of the strings bound to the patset in the current Text object then the result Text object has 0 length. The patset cannot have strings longer than 255 characters. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` text_t

`*AFTER_STR` (text_t s)

Selects the Text that is present after the first occurrence of the string argument. If there is no match for the argument in the current Text then the result Text object has 0 length. The input string cannot

be bigger than 255 characters. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*APPEND` (bool_at b)

Appends the given boolean's string representation to the current string.

`Parameters``:`

b- the boolean value to append.

`Returns:` text_t

`*APPEND` (double_at i)

Appends the given double's string representation to the current string.

`Parameters``:`

i- the double value to append.

`Returns:` text_t

`*APPEND` (ip_address_at addr)

Appends the given IPv4's string representation to the current string.

`Parameters``:`

addr- the IPv4 address to append.

`Returns:` text_t

`*APPEND` (num_at i)

Appends the given number's string representation to the current string.

`Parameters``:`

i- the number value to append.

`Returns:` text_t

`*APPEND` (time_local_at t)

Appends the given time's string representation to the current string.

`Parameters``:`

t- the time value to append.

`Returns:` text_t

`*APPEND` (time_at t)

Appends the given time's string representation to the current string.

`Parameters``:`

t- the time value to append.

`Returns:` text_t

`*APPEND` (unsigned_long_at i)

Appends the given unsigned long's string representation to the current string.

`Parameters``:`

i- the unsigned long value to append.

`Returns:` text_t

`*APPEND` (ipv6_address_at addr)

Appends the given IPv6's string representation to the current string.

`Parameters``:`

addr- the IPv6 address to append.

`Returns:` text_t

`*APPEND` (ipv6_subnet_at addr)

Appends the given IPv6 subnet's string representation to the current string.

`Parameters``:`

addr- the IPv6 subnet to append.

`Returns:` text_t

`*APPEND` (mac_address_at addr)

Appends the given MAC's string representation to the current string.

`Parameters``:`

addr- the MAC address to append.

`Returns:` text_t

`*APPEND` (text_t str)

Appends the given string to the current string.

`Parameters``:`

str- the string to append.

`Returns:` text_t

`*APPEND` (time_at t)

Appends the given time's string representation to the current string.

`Parameters``:`

t- the time value to append.

`Returns:` text_t

`*B64DECODE`

Decodes the selected text using base64 decoding.

For example, the string "TWFu" is converted to "Man"

`Returns:` text_t

`*B64ENCODE`

Encodes the selected text using base64 encoding.

For example, the string "Man" is converted to "TWFu"

`Returns:` text_t

`*BEFORE_REGEX` (`re` regex)

Selects the text before the portion that matches the given regular expression argument. The first match is returned when multiple matches occur in the text. The match may occur anywhere within the text - if you wish to "anchor" this, use "\^" at the start of the regex and/or "$" at the end of the regex. When the regular expression does not match the given string, a Text object of length of 0 is returned.

For example: HTTP.RES.HEADER("content-type").BEFORE_REGEX(re#/#) will select "text" from "text/plain". This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

regex- Regular Expression

`Returns:` text_t

`*BEFORE_STR_ANY` (text_t patset_name)

Selects the Text that is present before the first occurrence of any of the strings that are bound to the patset or datasetnamed by the string argument. If there is no match to any of the strings bound to the patset in the current Text object then the result Text object has 0 length. The patset cannot have strings longer than 255 characters. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` text_t

`*BEFORE_STR` (text_t s)

Selects the Text that is present before the first occurrence of the string argument. If there is no match for the argument in the current Text object then the result Text object has 0 length. The input string cannot be bigger than 255 characters. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*BETWEEN` (text_t start, text_t end)

Results in Boolean TRUE value if length of the Text object is greater than or equal to the sum of the Start and End argument lengths and if the prefix of the Text object matches the Start string argument and if the Suffix of the Text object matches the End string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

start- Start

end- End

`Returns:` bool_at

`*BIN_DECODE` (binary_encoding_e encoding)

Decode the encoded input into its original byte sequence. An incorrectly enooded input will result in an Undef error.

`Parameters` (expressions not allowed) `:`

encoding- specifies how the bytes are encoded.

`Returns:` text_t

`*BIN_ENCODE` (binary_encoding_e encoding)

Encode the input byte sequence. Note that BIN_ENCODE(hex_colons) is equivalent to BLOB_TO_HEX().

`Parameters` (expressions not allowed) `:`

encoding- specifies how the bytes are to be encoded.

`Returns:` text_t

`*BLOB_TO_HEX`

Convert to hexadecimal representation and select text.

For example, the byte string abc is converted to 61:62:63.

`Returns:` text_t

`*COMPARE` (text_t s)

Results in a Number Value which is the result of comparison of the input argument with the Text object. The result is greater than 0 if the Text object is lexicographically greater than the argument. The result is 0 if the Text object and the argument match. The result is less than 0 if the Text object is lexicographically lesser than the argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` num_at

`*CONTAINS_ANY` (text_t patset_name)

Results in Boolean TRUE value if the Text contains any of the strings that are bound to the patset or dataset named by the string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` bool_at

`*CONTAINS_INDEX` (text_t patset_name)

Returns the numerical index of the matching string, if the Text contains any of the strings that are bound to the patset or dataset named by the string argument. Returns 0 if there is no match. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` num_at

`*CONTAINS` (text_t s)

Results in Boolean TRUE value if the Text contains the string given in the argument. The input string cannot be bigger than 255 characters. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*CRC32`

Returns a 32-bit integer computed by applying a CRC (cyclic redundancy check) function to the selected text. This is the CRC function used by Ethernet, MPEG-2, PKZIP, GZIP, PNG, and many other applications. For example, the expression to compute the CRC value of the (first 1000 bytes of the) body of an HTTP request is: HTTP.REQ.BODY(1000).CRC32

`Returns:` num_at

`*DECODE_USING_TEXT_MODE`

Decodes the selected text using the currently configured text encoding methods like URLENCODED, BACKSLASH_ENCODED, PLUS_AS_SPACE, NOURLENCODED, NO_BACKSLASH_ENCODED and NO_PLUS_AS_SPACE. Text encoding methods are set using SET_TEXT_MODE method.

`Returns:` text_t

`*DECRYPT`

Decrypt the selected base64-encoded ciphertext using the configured encryptionParams.

`Returns:` text_t

`*DECRYPT` (binary_encoding_e in_encoding)

Decrypt the selected ciphertext using the configured encryptionParams.

`Parameters` (expressions not allowed) `:`

in_encoding- specifies how the input ciphertext is encoded. If the ciphertext is not encoded as specified, causes an Undef error.

`Returns:` text_t

`*DECRYPT` (text_t encryptionKey)

Decrypt the selected base64-encoded encrypted bytes using the configured encryption key.

`Parameters` (expressions not allowed) `:`

encryptionKey- identifies the encryptionKey object to provide the cipher method, mode, padding, key, encrypted format and optional initialization vector (IV).

`Returns:` text_t

`*DECRYPT` (text_t encryptionKey, binary_encoding_e in_encoding)

Decrypt the selected base64-encoded encrypted bytes using the configured encryption key.

`Parameters` (expressions not allowed) `:`

encryptionKey- identifies the encryptionKey object to provide the cipher method, mode, padding, key, encrypted format, and optional initialization vector (IV).

in_encoding- specifies how the input ciphertext is encoded. If the ciphertext is not encoded as specified, causes an Undef error.

`Returns:` text_t

`*DIGEST` (digest_method_e method)

Returns a byte sequence computed by applying the the specified message digest method to the selected text.

`Parameters` (expressions not allowed) `:`

method- digest method to apply to the input text

`Returns:` text_t

`*ENCRYPT`

Encrypt the selected plaintext bytes using the configured encryptionParams. The resulting ciphertext is base64-encoded.

`Returns:` text_t

`*ENCRYPT` (binary_encoding_e out_encoding)

Encrypt the selected plaintext bytes using the configured encryptionParams.

`Parameters` (expressions not allowed) `:`

out_encoding- specifies how the resulting ciphertext is encoded.

`Returns:` text_t

`*ENCRYPT` (text_t encryptionKey)

Encrypt the selected cleartext bytes using the configured encryption key.

`Parameters` (expressions not allowed) `:`

encryptionKey- identifies the encryptionKey object to provide the cipher method, mode, padding, key, encrypted format and optional initialization vector (IV).

`Returns:` text_t

`*ENCRYPT` (text_t encryptionKey, binary_encoding_e out_encoding)

Encrypt the selected cleartext bytes using the configured encryption key.

`Parameters` (expressions not allowed) `:`

encryptionKey- identifies the encryptionKey object to provide the cipher method, mode, padding, key, encrypted format and optional initialization vector (IV).

out_encoding- specifies how the resulting ciphertext is encoded.

`Returns:` text_t

`*ENDSWITH_ANY` (text_t patset_name)

Results in Boolean TRUE value if the Text ends with any of the strings that are bound to the patset or dataset named by the string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` bool_at

`*ENDSWITH_INDEX` (text_t patset_name)

Returns the numerical index of the matching string, if the Text ends with any of the strings that are bound to the patset or dataset named by the string argument. Returns 0 if there is no match. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` num_at

`*ENDSWITH` (text_t end)

Results in Boolean TRUE value if a suffix of the Text object matches the string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

end- String

`Returns:` bool_at

`*EQUALS_ANY` (text_t patset_name)

Results in Boolean TRUE value if the Text equals any of the strings that are bound to the patset or dataset named by the string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed)`:`

patset_name- Pattern Set Name

`Returns:` bool_at

`*EQUALS_INDEX` (text_t patset_name)

Returns the numerical index of the matching string, if the Text equals any of the strings that are bound to the patset or dataset named by the string argument. Returns 0 if there is no match. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed)`:`

patset_name- Pattern Set Name

`Returns:` num_at

`*EQ` (text_t s)

Results in Boolean TRUE value if the Text object matches the input argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*GET_SIGNED16` (`uint` n, endian_e endianness)

Get the 16-bit signed binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

endianness- Select little or big endian

`Returns:` num_at

`*GET_SIGNED32` (`uint` n, endian_e endianness)

Get the 32-bit signed binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

endianness- Select little or big endian

`Returns:` num_at

`*GET_SIGNED8` (`uint` n)

Get the 8-bit signed binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

`Returns:` num_at

`*GET_UNSIGNED16` (`uint` n, endian_e endianness)

Get the 16-bit unsigned binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

endianness- Select little or big endian

`Returns:` num_at

`*GET_UNSIGNED32` (`uint` n, endian_e endianness)

Get the 32-bit unsigned binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

endianness- Select little or big endian

`Returns:` unsigned_long_at

`*GET_UNSIGNED64` (`uint` n, endian_e endianness)

Get the 64-bit unsigned binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

endianness- Select little or big endian

`Returns:` unsigned_long_at

`*GET_UNSIGNED8` (`uint` n)

Get the 8-bit unsigned binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

`Returns:` num_at

`*GET_URLSET_METADATA` (text_t urlset_name)

Returns metadata value corresponding to pattern in the urlset. The matching is case-insensitive for domains, but case-sensitive for paths. If no pattern is matched within the urlset, the return value is a NULL string. For example:

- HTTP.REQ.HOST.APPEND(HTTP.REQ.URL).GET_URLSET_METADATA("urlset_forbidden") returns value when the combined domain and URL is looked up in the urlset whose name is "urlset_forbidden".

`Parameters` (expressions not allowed) `:`

urlset_name- urlset name

`Returns:` text_t

`*GE` (text_t s)

Results in Boolean TRUE value if the Text object is greater than or equal to the input argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*GRPC`

Interprets a text_t string as a Protocol Buffer (protocol_buffer_t type). Example: HTTP.REQ.BODY(1000).GRPC.STRING(1).EQ("bookname")

`Returns:` protocol_buffer_t

`*GT` (text_t s)

Results in Boolean TRUE value if the Text object is greater than the input argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*HASH`

Returns a positive 31 bit integer value computed by applying a proprietary NetScaler hash function to the selected text. This function is not case- sensitive and ignores whitespaces. For example, applying the HASH function to two strings "Ab c" and "abc" would produce the same value. This function should not be used for security purposes; use instead the DIGEST function with one of the standard digest methods.

`Returns:` num_at

`*HMAC` (text_t hmacKey)

Returns a byte sequence computed by applying the HMAC (Hash Message Authenticastion Code) function to the selected text using the configured HMAC key.

`Parameters` (expressions not allowed) `:`

hmacKey- indentifies the hmacKey object to provide the digest (hash) method and the key.

`Returns:` text_t

`*HMAC` (text_t hmacKey, binary_encoding_e out_encoding)

Returns a byte sequence computed by applying the HMAC (Hash Message Authenticastion Code) function to the selected text using the configured HMAC key .

`Parameters` (expressions not allowed) `:`

hmacKey- indentifies the hmacKey object to provide the digest (hash) method and the key.

out_encoding- specifies how the resulting HMAC is encoded.

`Returns:` text_t

`*HTML_XML_SAFE`

Apply XML safe transform and select text.

Converts '<', '>' and '&' in the input text to '<', '>' and '&' respectively; other characters in the input are not modified. This transform safeguards against XSS based attacks. This is a read only operation.

`Returns:` text_t

`*HTTP_HEADER_SAFE`

Apply Header safe transform and select text. Converts all new line ('\\n') characters present in the input text to '%0A' so that they can safely be used in HTTP headers. This transform safeguards against response-splitting attacks. This is a read only operation.

`Returns:` text_t

`*HTTP_URL_SAFE`

Apply URL safe transform and select text. Converts URL unsafe characters to corresponding '%xx' values and retains the rest. This is a read only operation.

```
Based on RFC2396, following are considered URL safe characters:

    Alpha-numeric characters: a-z, A-Z, 0-9

    Hyphen and underscore: "-", "_"

    Dot: "."

    Exclamation mark: "!"

    Tilde: "~"

    Asterix: "&ast;"

    Single quote: "'"

    Open and close parentheses: "(", ")"

    Semi-colon: ";"

    Colon: ":"

    At symbol: "@"

    Question mark: "?"

    Equals: "="

    Dollar: "$"

    Percent: "%"

    Ampersand: "&"

    Plus: "+"

    Comma: ","

    Forward slash: ".html"
```

The rest are converted to %XX encoding, 'XX' is the hex-based representation of the input character. If the requirement is to encode all but URL unreserved characters, please consider using URL_RESERVED_CHARS_SAFE method.

`Returns:` text_t

`*IS_BOOL_AT`

Results in Boolean TRUE value if the Text is of boolean type.

`Returns:` bool_at

`*IS_DOUBLE_AT`

Results in Boolean TRUE value if the Text is of double data type.

`Returns:` bool_at

`*IS_IPV6_AT`

Results in Boolean TRUE value if the Text is of IPv6 data type.

`Returns:` bool_at

`*IS_IPV6_SUBNET_AT`

Results in Boolean TRUE value if the Text is of IPv6 subnet data type.

`Returns:` bool_at

`*IS_IP_AT`

Results in Boolean TRUE value if the Text is of IPv4 data type.

`Returns:` bool_at

`*IS_MAC_ADDRESS_AT`

Results in Boolean TRUE value if the Text is of mac address data type.

`Returns:` bool_at

`*IS_NUM_AT`

Results in Boolean TRUE value if the Text is of number type.

`Returns:` bool_at

`*IS_NUM_AT` (num_format_e format)

Results in Boolean TRUE value if the Text is of number type with given input base.

`Parameters` (expressions not allowed) `:`

format- number format

`Returns:` bool_at

`*IS_STRINGMAP_KEY` (text_t string_map_name)

Returns true if the string that it operates on is present in the string map. Text mode IGNORECASE, NOIGNORECASE - controls whether key lookup in string map is case sensitive or not. For example:

- HTTP.REQ.URL.IS_STRINGMAP_KEY("url_stringmap") returns true if value of HTTP.REQ.URL is present as key in the string map whose name is "url_stringmap".
- HTTP.REQ.URL.SET_TEXT_MODE(IGNORECASE). IS_STRINGMAP_KEY("url_stringmap") returns true if value of HTTP.REQ.URL is present as key in the string map whose name is "url_stringmap". Key lookup in this case is done case-insensitively.

`Parameters` (expressions not allowed) `:`

string_map_name- identifies the string map.

`Returns:` bool_at

`*IS_TIME_AT`

Results in Boolean TRUE if the Text follows any of the standard time formats given below, otherwise false. Tue, 05 Nov 1994 08:12:31 GMT RFC822 Tuesday, 05-Nov-94 08:12:31 GMT RFC850 Tue Nov 4 08:12:31 1994 asctime

`Returns:` bool_at

`*IS_UNSIGNED_LONG_AT`

Results in Boolean TRUE value if the Text is of unsigned long data type.

`Returns:` bool_at

`*IS_UNSIGNED_LONG_AT` (num_format_e format)

Results in Boolean TRUE value if the Text is of unsigned long data type with given input base.

`Parameters` (expressions not allowed) `:`

format- number format

`Returns:` bool_at

`*JWT_VERIFY_CERTKEY` (text_t certkey_name)

Verifies the signature on the input JSON Web Token (JWT), using the RSA public key in the X.509 certificate in the specified certkey object. The token has the format HEADER.PAYLOAD.SIGNATURE where

- HEADER is a base64-encoded JSON structure indicating a signature algorithm and token type, e.g.'{"alg":"RS256","typ":"JWT"}'
- PAYLOAD is a base64-encoded JSON structure with asserted claims, e.g. '{"loggedInAs":"admin","iat":1422779638}'
- SIGNATURE is the base64-encoded bytes for the signature on HEADER.PAYLOAD.

Returns true if the signature is verified for the header and payload using the specified public key; false if the signature is not verified

`Parameters``:`

certkey_name- identifies the certkey object containing an X.509 certificate holding the RSA public key. Results in an Undef error if the certkey object does not exist or does not contain an X.509 certificate with an RSA public key, if the token is not correctly formatted, or if the verification operation cannot complete.

`Returns:` bool_at

`*JWT_VERIFY_XML` (text_t xml_pkey)

Verifies the signature on the input JSON Web Token (JWT), using the RSA public key supplied by the specified XML element. The token has the format HEADER.PAYLOAD.SIGNATURE where

- HEADER is a base64-encoded JSON structure indicating a signature algorithm and token type, e.g.'{"alg":"RS256","typ":"JWT"}'
- PAYLOAD is a base64-encoded JSON structure with asserted claims, e.g. '{"loggedInAs":"admin","iat":1422779638}'
- SIGNATURE is the base64-encoded bytes for the signature on HEADER.PAYLOAD.

Returns true if the signature is verified for the header and payload using the specified public key; false if the signature is not verified

`Parameters``:`

xml_pkey- an expression that supplies an <RSAKeyValue> element with the public key. Results in an Undef error if the XML element is invalid or does not correctly specify an RSA public key, if the token is not correctly formatted, or if the verification operation cannot complete.

`Returns:` bool_at

`*LENGTH`

Results in a Number Value that is the number of characters (not bytes) in the Text object.

`Returns:` num_at

`*LE` (text_t s)

Results in Boolean TRUE value if the Text object is less than or equal to the input argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*LOCATION_LONG`

Get the location qualifier from CLIENT.IP.SRC.LOCATION.GET(n) (ISO short name) and then convert it to human readable long name. This conversion is valid only for country names. Correct Country qualifier value (number) in GET(n) is left up to the user as qualifiers are user configurable. Expression example: CLIENT.IP.SRC.LOCATION.GET(1).LOCATION_LONG For example: Data from each expression CLIENT.IP.SRC.LOCATION: NA.US.California.SantaClara.*.* CLIENT.IP.SRC.LOCATION.GET(1): US CLIENT.IP.SRC.LOCATION.GET(1).LOCATION_LONG: United States

`Returns:` text_t

`*LT` (text_t s)

Results in Boolean TRUE value if the Text object is less than the input argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*MAP_STRING_DEFAULT_TO_KEY` (text_t string_map_name)

Returns the value corresponding to the key in the string map. This is similar to the MAP_STRING method, but if the key is not present then instead of returning a null string, it returns the key itself. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

string_map_name- identifies the string map.

`Returns:` text_t

`*MAP_STRING` (text_t string_map_name)

Returns value corresponding to key in the string map. Key is the string that it is given as input. Text mode IGNORECASE, NOIGNORECASE - controls whether key lookup in string map is case sensitive or not. For example:

- HTTP.REQ.URL.MAP_STRING("url_stringmap") returns value when the value of HTTP.REQ.URL is used as key in the string map whose name is "url_stringmap".
- HTTP.REQ.URL.SET_TEXT_MODE(IGNORECASE). MAP_STRING("url_stringmap") returns value when the value of HTTP.REQ.URL is used as key in the string map whose name is "url_stringmap". Key lookup in this case is done case-insensitively.

`Parameters` (expressions not allowed) `:`

string_map_name- identifies the string map.

`Returns:` text_t

`*MARK_SAFE`

Mark the PIXL expression safe without applying any safe transform.

`Returns:` text_t

`*MAX` (text_t s)

Compares the string argument with the current string and returns the max string. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*MIN` (text_t s)

Compares the string argument with the current string and returns the min string. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*NE` (text_t s)

Results in Boolean TRUE value if the Text object is not equal to the input argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*NORMALIZE_URL`

Normalize URL. Normalizes a URL by doing "percent" decoding. See the description for URLENCODED in the SET_TEXT_MODE function. This performs the equivalent of SET_TEXT_MODE(URLENCODED).DECODE_USING_TEXT_MODE, except that it does not change the value of the current text mode.

`Returns:` text_t

`*PKEY_ENCRYPT_PEM_NO_PADDING` (text_t pem_pkey)

Encrypts the input text using the RSA public key provided by the PEM string and RSA_NO_PADDING padding method. The input text to be encrypted cannot be longer than the public key length minus 11 bytes for padding. For example, for a 1024-bit (128 byte) key, the input

text cannot be longer than 128 - 11 = 117 bytes. An Undef error will occur if the input text is too long. A null input will also cause an Undef error. Returns the (unencoded binary) encrypted text, which is typically base-64 encoded for use in a message.

`Parameters``:`

pem_pkey- a text expression that supplies a RSA public key in the PEM format. If the text value is not a valid PEM RSA PUBLIC KEY encoding, an Undef error will occur. Example (a 1024-bit public key):

```
"-----BEGIN RSA PUBLIC KEY-----" +

"MIGJAoGBAKl5vgQEj73Kxp+9yn1v5gPR1pnc4oLM2a0kaWwBOsB6rzCIy6znwnvw" +

"CY1xRvQhRlJSAyJbloL7wZFIJ2FOR8Cz+8ZQWXU2syG+udi4EnWqLgFYowF9zK+o" +

"79az597eNPAjsHZ/C2oL/+6qY5a/f1z8bQPrHC4GpFfAEJhh/+NnAgMBAAE=" +

"-----END RSA PUBLIC KEY-----"
```

`Returns:` text_t

`*PKEY_ENCRYPT_PEM` (text_t pem_pkey)

Encrypts the input text using the RSA public key provided by the PEM string and the RSA_PKCS1_PADDING padding method. The input text to be encrypted cannot be longer than the public key length minus 11 bytes for padding. For example, for a 1024-bit (128 byte) key, the input text cannot be longer than 128 - 11 = 117 bytes. An Undef error will occur if the input text is too long. A null input will also cause an Undef error. Returns the (unencoded binary) encrypted text, which is typically base-64 encoded for use in a message.

`Parameters``:`

pem_pkey- a text expression that supplies a RSA public key in the PEM format. If the text value is not a valid PEM RSA PUBLIC KEY encoding, an Undef error will occur. Example (a 1024-bit public key):

```
"-----BEGIN RSA PUBLIC KEY-----" +

"MIGJAoGBAKl5vgQEj73Kxp+9yn1v5gPR1pnc4oLM2a0kaWwBOsB6rzCIy6znwnvw" +
```

```
"CY1xRvQhRlJSAyJbloL7wZFIJ2FOR8Cz+8ZQWXU2syG+udi4EnWqLgFYowF9zK+o" +

"79az597eNPAjsHZ/C2oL/+6qY5a/f1z8bQPrHC4GpFfAEJhh/+NnAgMBAAE=" +

"-----END RSA PUBLIC KEY-----"
```

`Returns:` text_t

`*PKEY_SIGN_CERTKEY` (text_t certkey_name)

Generates a binary digital signature using the SHA-256 message digest function and an RSA private key from the specified SSL certKey object.

`Parameters``:`

certkey_name- identifies the configured certKey object. Results in an Undef error if the certkey object does not exist or does not contain an RSA private key, or if the signing operation cannot complete.

`Returns:` text_t

`*PKEY_SIGN_XML` (text_t xml_pkey)

Generates a binary digital signature using the SHA-256 message digest function and an RSA private key from the specified XML element.

`Parameters``:`

xml_pkey- an expression that supplies an <RSAKeyValue> element with the private key. Example: <RSAKeyValue> <Modulus>qXm+BASPvcrGn73KfW/
mA9HWmdzigszZrSRpbAE6wHqvMIjLrOfCe/
AJjXFG9CFGUlIDIluWgvvBkUgnYU5HwLP7xlBZdTazIb652LgSdaouAVijAX3Mr6jv1rPn3t408COwdn8Lagv/
7qpjlr9/XPxtA+scLgakV8AQmGH/42c=</Modulus> <Exponent>AQAB</Exponent>"zNjysxcIJV/
J9cTpIgPp2/x1IXHT5GTH8OMuNad0qtRSLjU1QYUmmkm9QcJJAN+7h8FEXWGabySUzBrHj/
IEbw=="
<DP>QavUDQLLQpnPJXtVAo6CYhxOMCd68mwTxYKKNLjmC0pd54SFHllTLPE1FZU5EjK6q3nCeijonpfH+XX
DP> <DQ>EiXOKouJzzXTQJC3TqomF7Uf81yQNxWumOqnd11kepXgyfMwyqMvLlAGEkNSEF/

nw==</InverseQ> <D>fTBD773a3GzcmgVdfZlaBLpN1ux2mf5uUVrTUQf7eVFm9egm4/
tzC5A9zjC+I/oscwTH8epL3UfRLdtp05Q6pWfJBXEnGo0QmOFFBK4pLx/

5JJpPGZ69ovDFEVOUHyiCfKE/g97T4WX3us0nFe1272zwGlHarM1YYwvfeE08UdE=</D> </RSAKeyValue> Results in an Undef error if the XML element is invalid or does not correctly specify an RSA private key, or if the signing operation cannot complete.

`Returns:` text_t

`*PKEY_VERIFY_CERTKEY` (text_t certkey_name, text_t signature)

Verifies if the input text matches the specified signature generated using the SHA-256 messge digest function and the RSA private key associated with the specified RSA public key in the X.509 certificate in the specified certKey object. Returns true if the signature is verified, false otherwise.

`Parameters``:`

certkey_name- identifies the certkey object containing an X.509 certificate holding the RSA public key.

signature- the binary signature. Results in an Undef error if the certkey object does not exist or does not contain an X.509 certificate with an RSA public key, or if the verification operation cannot complete.

`Returns:` bool_at

`*PKEY_VERIFY_XML` (text_t xml_pkey, text_t signature)

Verifies if the input text matches the specified signature generated using the SHA-256 messge digest function and the RSA private key associated with the RSA public key supplied by the specified XML element. Returns true if the signature is verified, false otherwise.

`Parameters``:`

xml_pkey- an expression that supplies an <RSAKeyVAlue> element with the public key. Example: <RSAKeyValue> <Modulus>qXm+BASPvcrGn73KfW/mA9HWmdzigszZrSRpbAE6wHqvMIjLrOfCe/AJjXFG9CFGUlIDIluWgvvBkUgnYU5HwLP7xlBZdTazIb652LgSdaouAVijAX3Mr6jv1rPn3t408COwdn8Lagv/7qpjlr9/XPxtA+scLgakV8AQmGH/42c=</Modulus> <Exponent>AQAB</Exponent> </RSAKeyValue>

signature- the binary signature. Results in an Undef error if the XML element is invalid or does not correctly specify an RSA public key, or if the verification operation cannot complete.

`Returns:` bool_at

`*PREFIX` (`char` c, `uint` i)

Select a prefix of the Text. The selected prefix is the longest prefix that has at most Count (2nd argument) occurrences of character in the 1st argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

c- Character

i- Count

`Returns:` text_t

`*PREFIX` (`uint` i)

Select a prefix of the Text. The length of the prefix is equal to the number in the argument. If there aren't enough characters in the Text object then the entire Text is selected.

`Parameters``:`

i- Prefix Length

`Returns:` text_t

`*REGEX_MATCH` (`re` regex)

Returns TRUE if and only if the text contains at least one match of the regular expression argument. The match may occur anywhere within the text - if you wish to "anchor" this, use "\^" at the start of the regex and/or "$" at the end of the regex.

The regular expression has to be of the format: `re<delimiter>regular expression<same delimiter>`

The regular expression cannot be bigger than 1499 characters.

The regular expression should be acceptable by the PCRE regular expression library. Look at http://www.pcre.org/pcre.txt for documentation on the regular expression syntax. In particular, look at the pcrepattern man page.

There are some differences in the allowed syntax w.r.t PCRE syntax. Backreferences are not allowed. It is recommended not to use recursive regular expressions. The dot metacharacter

matches newlines also. Unicode is not supported. SET_TEXT_MODE(IGNORECASE) overrides the (?i) internal option specified in the regular expression.

The PCRE library configuration can be seen in the system log, after executing 'nsapimgr -B" call ns_pixl_regex_show_config()"' at the shell prompt.

Some examples:

- HTTP.REQ.HOSTNAME.REGEX_MATCH(re/\[\[:alpha:\]\]+(abc){2,3}/)
- HTTP.REQ.URL.SET_TEXT_MODE(URLENCODED).REGEX_MATCH(re#(a*b+c*)#)
- HTTP.REQ.URL.REGEX_MATCH(re/a(?i)b/) matches ab and aB
- HTTP.REQ.URL.SET_TEXT_MODE(IGNORECASE).REGEX_MATCH(re/ab/) matches ab, aB, Ab and AB
- HTTP.REQ.BODY.REGEX_MATCH(re/(?ixm) (\^ab (.*) cd$) /) does a case-insensitive, multiline match where the dot metacharacter matches newline also. The regex itself can contain whitespace which will be ignored during the matching (x - extended regex).

This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

regex- Regular Expression

`Returns:` bool_at

`*REGEX_REPLACE` (`re` regex, text_t replacement, replacemode_e mode)

Selects the text that matches the given regular expression argument and replaces it with the the text given in the second argument. The third argument specifies whether the first match is only replaced when multiple matches occur in the text or all matches are replaced. The match may occur anywhere within the text - if you wish to "anchor" this, use "\^" at the start of the regex and/or "$" at the end of the regex. When the regular expression does not match the given string then the same string is returned.

For example: HTTP.RES.BODY(999).REGEX_REPLACE(re!\\bpassword:\\s*\\b!, "password: ***", ALL) will replace all occurrences of "password:" with "password: ***" This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

regex- Regular Expression

replacement- String to replace the match

mode- Mode of replacement

`Returns:` text_t

`*REGEX_SELECT` (`re` regex)

Selects the text that matches the given regular expression argument. The first match is returned when multiple matches occur in the text. The match may occur anywhere within the text - if you wish to "anchor" this, use "\^" at the start of the regex and/or "$" at the end of the regex. When the regular expression does not match the given string, a Text object of length of 0 is returned.

For example: HTTP.REQ.HEADER("via").REGEX_SELECT(re!NS-CACHE-\\d\\.\\d:\\s*\\d{1,3}!) will select "NS-CACHE-7.0: 70" This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

regex- Regular Expression

`Returns:` text_t

`*REPEAT` (`uint` i)

Produces a string which contains 'i' sequential copies of the input string.

`Parameters``:`

i- the number of times to repeat the string (0 or more)

`Returns:` text_t

`*SET_CHAR_SET` (charset_e charset)

Set the character set to use for subsequent functions that use text.

`Parameters` (expressions not allowed) `:`

charset- Character Set

`Returns:` dns_flag_t

`*SET_TEXT_MODE` (textmode_e mode)

The mode setting of a Text object controls the behavior of many Text operations. The Text mode settings may also control the behavior of some operations in objects (like List) that build upon the Text object. IGNORECASE, NOIGNORECASE - controls whether string comparison is case sensitive or not. URLENCODED - If set then all Text operations are carried out after translating all %HH or %uHHHH encodings in the underlying byte stream. 1. %HH will be translated to the character Y where HH denotes the ascii value of character Y in hexadecimal. For example, the encoded text "http%3a/.html" will be decoded to "http:/.html" 2. %uWWHH will be translated to the character sequence YZ where WW denotes the ascii value of character Y in hexadecimal and HH denotes the ascii value of character Z in hexadecimal. For example, the encoded text "http%u3a2f.html" and "http%u003a/.html" will both be decoded to"http:/.html" NOURLENCODED - Indicates that no percent encodings are present in the Text object. No percent decoding will be performed on the Text object. PLUS_AS_SPACE - If set then all Text operations are carried out after converting occurrences of the plus character to whitespace. For example, the text "hello+world" will be decoded to "hello world" NO_PLUS_AS_SPACE - If set, then the plus character will not be converted to whitespace in the Text object. BACKSLASH_ENCODED - If set, then all Text operations are carried out after performing the following operations: 1. \\XXX will be translated to the character Y where XXX denotes the ascii value of character Y in octal. The valid range of octal values for this type of encoding is \\0 to \\377. For example, the encoded text "http\\72/.html" and "http\\072/.html" will both be decoded to "http:/.html" 2. \\xHH will be translated to the character Y where HH denotes the ascii value of character Y in hexadecimal. For example, the encoded text "http\\x3a/.html" will be decoded to "http:/.html" 3. \\\\uWWXX will be translated to the character sequence YZ where WW denotes the ascii value of character Y in hexadecimal and XX denotes the ascii value of character Z in hexadecimal. For example, the encoded text "http%u3a2f.html" and "http%u003a/.html" will both be decoded to"http:/.html" 4. Occurences of "\\b", "\\n", "\\t", "\\f" and "\\r" are translated to the corresponding ascii characters. NO_BACKSLASH_ENCODED - If set, then backslash decoding will not be performed on the Text object. BAD_ENCODE_RAISE_UNDEF - If set, then UNDEF is raised if either the URLENCODED or BACKSLASH_ENCODED mode is set and a bad encoding corresponding to the specified encoding mode is encountered. NO_BAD_ENCODE_RAISE_UNDEF - If set, then UNDEF will not be raised when a bad encoding is encountered in the Text object. The Text operations operate on characters (as opposed to operating on bytes). By default a single byte represents a character using the ASCII encoding. But if URLENCODED mode is set then 3 bytes may represent a character. A PREFIX(3) operation will select the first 3 characters in the Text object. That means it may select up to 9 bytes for URLENCODED Text object. In the case of multibyte decodings as a result of %uXXXX or \\\\uXXXX, Text operations which attempt to treat the multiple decoded bytes as distinct characters are not allowed.

`Parameters` (expressions not allowed) `:`

mode- Text Mode

`Returns:` dns_flag_t

`*SKIP` (`char` c, `uint` i)

Select the Text after skipping over a prefix of the current Text. The skipped over prefix is the longest prefix that has at most Count (2nd argument) occurrences of character in the 1st argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

c- Character

i- Count

`Returns:` text_t

`*SKIP` (`uint` i)

Select the Text after skipping over a prefix in the current Text. The length of the prefix is equal to the number in the argument. If there aren't enough characters in the Text object then the entire Text is skipped over.

`Parameters` (expressions not allowed) `:`

i- Prefix Length

`Returns:` text_t

`*STARTSWITH_ANY` (text_t patset_name)

Results in Boolean TRUE value if the Text starts with any of the strings that are bound to the patset or dataset named by the string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` bool_at

`*STARTSWITH_INDEX` (text_t patset_name)

Returns the numerical index of the matching string, if the Text starts with any of the strings that are bound to the patset or dataset named by the string argument. Returns 0 if there is no match. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` num_at

`*STARTSWITH` (text_t start)

Results in Boolean TRUE value if a prefix of the Text object matches the string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

start- String

`Returns:` bool_at

`*STRIP_CHARS` (text_t s)

From the selected text remove the characters specified in the string.

For example: Say the selected text is / "foo.xyz=bar" /. Then on executing STRIP_CHARS('.=') or STRIP_CHARS('..=') the selected text will become /fooxyzbar /. Note that repeating character has same effect as it would be if it present only once. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*STRIP_END_CHARS` (text_t s)

Selects the Text after stripping off characters in the end of the current Text object.

For example: Say the selected text is / "foo.xyz=bar" /. Then on executing STRIP_END_CHARS('ar') the selected text will become /foo.xyz=b /. Note that repeating character has same effect as it would be if it present only once. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*STRIP_END_WS`

Selects the Text after stripping off white space in the end of the current Text object.

`Returns:` text_t

`*STRIP_START_CHARS` (text_t s)

Selects the Text after stripping off characters in the beginning of the current Text object.

For example: Say the selected text is / "foo.xyz=bar" /. Then on executing STRIP_START_CHARS('of') the selected text will become /.xyz=bar /. Note that repeating character has same effect as it would be if it present only once. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*STRIP_START_WS`

Selects the Text after stripping off white space in the beginning of the current Text object.

`Returns:` text_t

`*SUBSTR_ANY` (text_t patset_name)

Select any one sub-string that matches any string in the given patset or dataset. The patset cannot have strings longer than 255 characters. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed)`:`

patset_name- Pattern Set Name

`Returns:` text_t

`*SUBSTR` (`uint` start, `uint` len)

Select the Text object of the given length at the given offset. Offset it 0 based. If there aren't enough characters after the offset then all the remaining characters are selected.

`Parameters``:`

start- Offset

len- Length

`Returns:` text_t

`*SUBSTR` (text_t s)

Select the first Text object that matches the input string argument. The input string cannot be bigger than 255 characters. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*SUFFIX` (`char` c, `uint` i)

Select a suffix of the Text. The selected suffix is the longest possible suffix containing at most Count (2nd arg) occurrences of the character in the 1st argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

c- Character

i- Count

`Returns:` text_t

`*SUFFIX` (`uint` i)

Select a suffix of the Text. The length of the suffix is equal to the number in the argument. If there aren't enough characters in the Text object then the entire Text is selected.

`Parameters``:`

i- Suffix Length

`Returns:` text_t

`*TO_LOWER`

Converts the selected text to lower case.

For example, the string "ABCd" is converted to "abcd"

`Returns:` text_t

`*TO_UPPER`

Converts the selected text to upper case.

For example, the string "abcD" is converted to "ABCD"

`Returns:` text_t

`*TRUNCATE` (`char` c, `uint` i)

Select the Text after truncating a suffix from the current Text object. The truncated suffix is the longest possible suffix containing at most Count (2nd arg) occurrences of the character in the 1st argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

c- Character

i- Count

`Returns:` text_t

`*TRUNCATE` (`uint` i)

Select the Text after truncating a suffix of the Text. The length of the suffix truncated is equal to the number in the argument. If there aren't enough characters in the Text then then all the characters are truncated.

`Parameters``:`

i- Suffix Length

`Returns:` text_t

`*TYPECAST_AVP_T`

Convert text_t to avp_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (avp_t : Operations that can be performed on the returned AVPs.

`Note:` An AVP can have multiple instances in a Diameter message. However, the system can access only the first 16 instances.

`Example:`

- To get the first value of AVP code 266 from a request, use: DIAMETER.REQ.AVP(266).VALUE(0).
- To get the fourth value of AVP code 266 from a request, use: DIAMETER.REQ.AVP(266).VALUE(3).
- To check if AVP code 1000 in the response has the vendor-specific bit set, use: DIAMETER.RES.AVP(1000).IS_VENDOR_SPECIFIC.

)

`Returns:` avp_t

`*TYPECAST_AVP_UNUM_T`

Convert text_t to avp_unum_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (avp_unum_t : In Diameter AVP based expressions can be written as DIAMETER.REQ.AVP(<avpcode>). For example Auth-Application-Id AVP (AVP code 258) can be extracted as DIAMETER.REQ.AVP(258) For few of the important AVPs we provide aliases. For example this AVP based expression can also be written as DIAMETER.REQ.AUTH_APPLICATION_ID. This expression returns either a object of class avp_t or returns a numerical value (object of class unsigned_long_at). The numerical value for this object is derived from the value in first instance of the AVP.)

`Returns:` avp_unum_t

`*TYPECAST_BOOL_AT`

Convert text_t to bool_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (bool_at : Boolean Operations)

`Returns:` bool_at

`*TYPECAST_COOKIE_T`

Convert text_t to cookie_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (cookie_t : The HTTP Cookie type provides operations for a cookie as it appears in the Set-Cookie and Set-Cookie2 header. In this type the Name-Value List operations are also available. The first delimiter is = and the element delimiter is ;. Multiple consecutive ; are treated as one. (Same as applying the method IGNORE_EMPTY_ELEMENTS on a Name-Value List.) You can use the Name-value List operations to access cookie attributes. The name comparison for all list operations is case insensitive. In this type Text operations are also available. Each cookie begins with a COOKIE_NAME=COOKIE_VALUE pair followed by zero or more semi-colon separated attribute-value pairs. If an attribute appears more than once in a cookie, the value associated with the first appearance of the attribute is returned.

Format Cookie: Cookie1=Value;Version=decimal;Value;Domain=Value;Path=Value)

`Returns:` cookie_t

`*TYPECAST_DIAMETER_FLAG_T`

Convert text_t to diameter_flag_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (diameter_flag_t : Provides operation to treat the underlying 1 byte as set of bit flags. then set/unset/test/reset_all operations can be done on flag)

`Returns:` diameter_flag_t

`*TYPECAST_DNS_DOMAINNAME_T`

Convert text_t to dns_domainname_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (dns_domainname_t : This object provides operations for parsing the DNS domain name as it appears at various places in the DNS data. The format is abc.foo.com.)

`Returns:` dns_domainname_t

`*TYPECAST_DNS_FLAG_T`

Convert text_t to dns_flag_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (dns_flag_t : Provides operations to test/set/unset a flag in dns header.)

`Returns:` dns_flag_t

`*TYPECAST_DOUBLE_AT`

Convert text_t to double_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_at : Double Value)

`Returns:` double_at

`*TYPECAST_DOUBLE_T` (double_format_e format)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error.)

`Parameters` (expressions not allowed) `:`

format- Format

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, double_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, ip_address_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given

format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, num_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, time_local_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, time_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, unsigned_long_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_HTTP_CACHE_CONTROL_T`

Convert text_t to http_cache_control_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_cache_control_t : This object provides for the ability to work on HTTP Cache-Control headers. The name comparison for all list operations is case insensitive.)

`Returns:` http_cache_control_t

`*TYPECAST_HTTP_CONTENT_LENGTH_T`

Convert text_t to http_content_length_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_content_length_t : The HTTP.REQ.CONTENT_LENGTH or HTTP.RES.CONTENT_LENGTH object can be treated as a HTTP Header or as a Number. The numerical value for this object is derived from the value in the last instance of the Content-Length header.)

`Returns:` http_content_length_t

`*TYPECAST_HTTP_COOKIE_T`

Convert text_t to http_cookie_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_cookie_t : This object provides operations for parsing the HTTP cookie header. The name-value pair is derived from the value in the last instance of Cookie header. The format is Cookie : name0=value0; name1=value1; An HTTP Cookie header can have multiple occurrences. COUNT will return a Number containing how many headers of the current type exist. The name comparison for all list operations is case insensitive. The system does not keep track of more than 15 HTTP headers. The result will be undefined if there are more than 15 instances of the header.)

`Returns:` http_cookie_t

`*TYPECAST_HTTP_DATE_T`

Convert text_t to http_date_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_date_t : The HTTP.REQ.DATE or HTTP.RES.DATE object can be treated as a HTTP header or a Time object. The Time value is derived from the value in the last instance of the Date header. The date formats supported are RFC 822 (updated by RFC 1123), RFC 1036 (obsoletes RFC850) and ANSI C asctime() formats.)

`Returns:` http_date_t

`*TYPECAST_HTTP_HEADER_T` (text_t name)

Convert text_t to http_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_header_t : When typecasting a Text object to HTTP Header a header name must be provided.For example: HTTP.REQ.HEADER("MyHdr").TYPECAST_HTTP_HEADER_T("InHdr"))

`Parameters` (expressions not allowed) `:`

name- Header Name

`Returns:` http_header_t

`*TYPECAST_HTTP_HOSTNAME_T`

Convert text_t to http_hostname_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_hostname_t : This object provides operations for parsing the HTTP hostname as it appears at various places in the HTTP protocol data. The format is abc.foo.com:8080.)

`Returns:` http_hostname_t

`*TYPECAST_HTTP_METHOD_T`

Convert text_t to http_method_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_method_t : This object provides Text operations and HTTP Request Method Enum operations on the HTTP request method.)

`Returns:` http_method_t

`*TYPECAST_HTTP_SET_COOKIE_T`

Convert text_t to http_set_cookie_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_set_cookie_t : HTTP.RES.SET_COOKIE provides operations for parsing and operating on the SET-COOKIE header that is present in the HTTP response. HTTP Set-Cookie header supports Text and HTTP Header operations. For most Text operations the value in the last Set-Cookie header is selected. HTTP Set-Cookie header also supports special operations to extract cookies from the response. It is assumed that there will be only one cookie in a Set-Cookie header.)

`Returns:` http_set_cookie_t

`*TYPECAST_HTTP_URL_T`

Convert text_t to http_url_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_url_t : HTTP.REQ.URL provides operations for parsing and operating on the URL that is present in the first line of the HTTP request header. The supported format is \[<protocol>://<hostname>\]<path>?<query>. The Text object backing a HTTP URL object has the Text Mode set to URLENCODED by default.)

`Returns:` http_url_t

`*TYPECAST_HTTP_VERSION_T`

Convert text_t to http_version_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_version_t : HTTP.REQ.VERSION or HTTP.RES.VERSION provide operations to extract HTTP version information.)

`Returns:` http_version_t

`*TYPECAST_IPV6_ADDRESS_AT`

Convert text_t to ipv6_address_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ipv6_address_at : Provides operations for the 128-bit IPv6 address value. Some general information regarding IPv6 expressions: IPv6 PIXL expressions can be combined with other PIXL expressions using the '+' operator. The output is expected to be the concatenation of the string representations of the individual PIXL expressions. No other operator other than '+' is expected to work when any of the operands is an IPv6 PIXL expression. Also, IPv6 PIXL expressions can be combined with any other type of PIXL expression except a PIXL expression that produces a bool result. In other words, if A and/or B are two IPv6 addresses, A+B should result in the string AB. When one of A or B is an IPv6 address, the other can only be a number or a string and not a boolean. Further, when A and/or B is an IPv6 address, the only operator allowed between them is '+'.

Example: Let the client source IPv6 address be ABCD:1234::ABCD. Let the server destination IPv4 address be 10.100.10.100. Then the expression CLIENT.IPV6.SRC + SERVER.IP.DST should produce the output "ABCD:1234::ABCD10.100.10.100". Similarly, CLIENT.IPV6.SRC + 5 should produce the result ABCD:1234::ABCD5)

`Returns:` ipv6_address_at

`*TYPECAST_IPV6_ADDRESS_T`

Convert text_t to ipv6_address_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ipv6_address_t : This object represents an IPv6 address present in the 1000:1001:CD10:0000:0000:89AB:4567:CDEF format.)

`Returns:` ipv6_address_t

`*TYPECAST_IPV6_SUBNET_AT`

Convert text_t to ipv6_subnet_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ipv6_subnet_at : Provides operations for the integral IPv6 subnet address value.)

`Returns:` ipv6_subnet_at

`*TYPECAST_IPV6_SUBNET_T`

Convert text_t to ipv6_subnet_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ipv6_subnet_t : This object represents an IPv6 subnet address present in the 1000:1001:CD10:0000:0000:89AB:4567:CDEF/64 format.)

`Returns:` ipv6_subnet_t

`*TYPECAST_IP_ADDRESS_AT`

Convert text_t to ip_address_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ip_address_at : Provides operations for the 32-bit integral IP address value.)

`Returns:` ip_address_at

`*TYPECAST_IP_ADDRESS_T`

Convert text_t to ip_address_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ip_address_t : Represents an IP address present in the 10.100.200.1 format.)

`Returns:` ip_address_t

`*TYPECAST_IP_OPTIONS_T`

Convert text_t to ip_options_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ip_options_t : IP protocol options)

`Returns:` ip_options_t

`*TYPECAST_IP_OPTIONS_TYPE_T`

Convert text_t to ip_options_type_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ip_options_type_t : IP Options Type)

`Returns:` ip_options_type_t

`*TYPECAST_IP_TOS_T`

Convert text_t to ip_tos_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ip_tos_t : Provides operations to TOS field in IP header.)

`Returns:` ip_tos_t

`*TYPECAST_LIST_T` (`char` sep)

Convert text_t to list_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (list_t : The character separator has to be provided when typecasting a textual context to list type. The current text mode has no effect on the character separator. For example if the current text mode is IGNORECASE and the separator is p then P will not be treated as a separator.)

`Parameters` (expressions not allowed) `:`

sep- Separator

`Returns:` list_t

`*TYPECAST_MAC_ADDRESS_AT`

Convert text_t to mac_address_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (mac_address_at : Provides operations for the 48-bit MAC address value.)

`Returns:` mac_address_at

`*TYPECAST_MAC_ADDRESS_T`

Convert text_t to mac_address_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (mac_address_t : Represents a MAC address present in the 12:34:56:78:9a:bc format.)

`Returns:` mac_address_t

`*TYPECAST_NUM_AT`

Convert text_t to num_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (num_at : Number Value)

`Returns:` num_at

`*TYPECAST_NUM_T` (num_format_e format)

Convert text_t to num_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (num_t : Treat the underlying text as a Number in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error.)

`Parameters` (expressions not allowed) `:`

format- Format

`Returns:` num_t

`*TYPECAST_NUM_T` (num_format_e format, num_at default_value)

Convert text_t to num_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (num_t : Treat the underlying text as a Number in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` num_t

`*TYPECAST_NVLIST_T` (`char` sep1, `char` sep2)

Convert text_t to nvlist_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (nvlist_t : Two character delimiters have to be provided when typecasting a Text object to a Name-Value List. The first delimited separates the name from the value. The second delimiter separates list items. For example typecast_nvlist_t('=', '&') handles a URL query string. The Text Mode has no effect on the character delimiters. For example if the current text mode is IGNORECASE and a delimiter is p then P will not be treated as a delimiter.)

`Parameters` (expressions not allowed) `:`

sep1- delimiter1

sep2- delimiter2

`Returns:` nvlist_t

`*TYPECAST_NVLIST_T` (`char` sep1, `char` sep2, `char` quote)

Convert text_t to nvlist_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (nvlist_t : Two character delimiters and quote-character have to be provided when typecasting a Text object to a Name-Value List that supports quote-character. The first delimited separates the name from the value. The second delimiter separates list items. The third value specifies the quote character. For example typecast_nvlist_t('=', ';', "") handles a name-value list separated by semi-colons that allows quoting. The quote-character specifies that the value can occur within the quotes and the delimiters within the quote-characters should not be taken into account. The Text Mode has no effect on the character delimiters. For example if the current text mode is IGNORECASE and a delimiter is p then P will not be treated as a delimiter.)

`Parameters` (expressions not allowed) `:`

sep1- delimiter1

sep2- delimiter2

quote- quote-character.

`Returns:` nvlist_t

`*TYPECAST_PROTOCOL_BUFFER_T`

Convert text_t to protocol_buffer_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (protocol_buffer_t : gRPC Protocol Buffers interface)

`Returns:` protocol_buffer_t

`*TYPECAST_RADIUS_AVP_T`

Convert text_t to radius_avp_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (radius_avp_t : Operations that can be performed on the returned AVPs.

`Note:` An AVP can have multiple instances in a radius message. However, the system can access only the first 16 instances.

`Example:`

- To get the first value of AVP code 26 from a request, use: radius.REQ.AVP(26).VALUE(0).
- To get the fourth value of AVP code 26 from a request, use: radius.REQ.AVP(26).VALUE(3).

)

`Returns:` radius_avp_t

`*TYPECAST_RADIUS_AVP_VALUE_T`

Convert text_t to radius_avp_value_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (radius_avp_value_t : Provides operations to typecast RADIUS AVP value to Integer value or IP Address.)

`Returns:` radius_avp_value_t

`*TYPECAST_SEQ_TEXT_T`

Convert text_t to seq_text_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (seq_text_t : Represents the Text Sequence class.)

`Returns:` seq_text_t

`*TYPECAST_SERVICEPATH_T`

Convert text_t to servicepath_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (servicepath_t : Operations that can be performed on the service path.

`Example:`

- To get the name of the service path applicable to current subscriber, use: SUBSCRIBER.SERVICEPATH

- To determine If the service function is the next in the service path applicable to scubscriber, use: SUBSCRIBER.SERVICEPATH.IS_NEXT().

)

`Returns:` servicepath_t

`*TYPECAST_SIP_CALLID_HEADER_T`

Convert text_t to sip_callid_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_callid_header_t : This object provides operations for parsing the SIP callid header.)

`Returns:` sip_callid_header_t

`*TYPECAST_SIP_CONTENT_LENGTH_T`

Convert text_t to sip_content_length_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_content_length_t : The SIP.REQ.CONTENT_LENGTH or SIP.RES.CONTENT_LENGTH object can be treated as a SIP Header or as a Number. The numerical value for this object is derived from the value in the last instance of the Content-Length header.)

`Returns:` sip_content_length_t

`*TYPECAST_SIP_FROM_HEADER_T`

Convert text_t to sip_from_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_from_header_t : This object provides operations for parsing the SIP From header.)

`Returns:` sip_from_header_t

`*TYPECAST_SIP_HEADER_T` (text_t name)

Convert text_t to sip_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_header_t : When typecasting a Text object to SIP Header a header name must be provided.For example: SIP.REQ.HEADER("MyHdr").TYPECAST_SIP_HEADER_T("InHdr"))

`Parameters` (expressions not allowed) `:`

name- Header Name

`Returns:` sip_header_t

`*TYPECAST_SIP_HOSTNAME_T`

Convert text_t to sip_hostname_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_hostname_t : This object provides operations for parsing the SIP hostname as it appears at various places in the SIP protocol data. The format is abc.foo.com:5060.)

`Returns:` sip_hostname_t

`*TYPECAST_SIP_METHOD_T`

Convert text_t to sip_method_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_method_t : This object provides Text operations and SIP Request Method Enum operations on the SIP request method.)

`Returns:` sip_method_t

`*TYPECAST_SIP_TO_HEADER_T`

Convert text_t to sip_to_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_to_header_t : This object provides operations for parsing the SIP From header.)

`Returns:` sip_to_header_t

`*TYPECAST_SIP_URL_T`

Convert text_t to sip_url_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_url_t : SIP.REQ.URL provides operations for parsing and operating on the URL that is present in the first line of the SIP request header. The supported format is \[<protocol>://<hostname>\]<path>?<query>. The Text object backing a SIP URL object has the Text Mode set to URLENCODED by default.)

`Returns:` sip_url_t

`*TYPECAST_SIP_VERSION_T`

Convert text_t to sip_version_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_version_t : SIP.REQ.VERSION or SIP.RES.VERSION provide operations to extract SIP version information.)

`Returns:` sip_version_t

`*TYPECAST_SIP_VIA_HEADER_T`

Convert text_t to sip_via_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_via_header_t : This object provides operations for parsing the SIP Via header.)

`Returns:` sip_via_header_t

`*TYPECAST_SSLVPN_MODE_T`

Convert text_t to sslvpn_mode_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sslvpn_mode_t : This object provides Text operations and SSLVPN Mode Enum operations on the SSLVPN request method.)

`Returns:` sslvpn_mode_t

`*TYPECAST_SSL_TEXT_T` (text_t name)

Convert text_t to ssl_text_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ssl_text_t : Treat the underlying text object as SSL Text.)

`Parameters` (expressions not allowed) `:`

name- Name

`Returns:` ssl_text_t

`*TYPECAST_TCP_OPTIONS_T`

Convert text_t to tcp_options_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (tcp_options_t : TCP Protocol Options)

`Returns:` tcp_options_t

`*TYPECAST_TCP_OPTIONS_TYPE_T`

Convert text_t to tcp_options_type_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (tcp_options_type_t : TCP Protocol Options Type)

`Returns:` tcp_options_type_t

`*TYPECAST_TCP_REPEATER_OPTION_T`

Convert text_t to tcp_repeater_option_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (tcp_repeater_option_t : TCP Protocol Option : Repeater)

`Returns:` tcp_repeater_option_t

`*TYPECAST_TIME_AT`

Convert text_t to time_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (time_at : Treats a number value as number of seconds since GMT Jan 1 1970 0h 0m 0s.)

`Returns:` time_at

`*TYPECAST_TIME_LOCAL_AT`

Convert text_t to time_local_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (time_local_at : Treats a number value as number of seconds since GMT Jan 1 1970 0h 0m 0s as adjsuted for the local time zone.)

`Returns:` time_local_at

`*TYPECAST_TIME_T`

Convert text_t to time_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (time_t : This object treats a Text object as a date string. The formats supported are

1\. RFC822 :: Sun, 06 Nov 1994 08:49:37 GMT 2\. RFC850 :: Sunday, 06-Nov-94 08:49:37 GMT 3\. ASCTIME :: Sun Nov 6 08:49:37 1994 4\. ASCTIME like :: Sun Nov 6 08:49:37 1994 5\. ASCTIME like :: Sun Nov 06 08:49:37 1994 6\. Http Set-Cookie Expiry date :: Sun, 06-Nov-1994 08:49:37 GMT)

`Returns:` time_t

`*TYPECAST_UNSIGNED_LONG_AT`

Convert text_t to unsigned_long_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_at : Unsigned Long(64bit) Value)

`Returns:` unsigned_long_at

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error.)

`Parameters` (expressions not allowed) `:`

format- Format

`Returns:` unsigned_long_t

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format, ip_address_at default_value)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` unsigned_long_t

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format, unsigned_long_at default_value)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining

characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` unsigned_long_t

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format, num_at default_value)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` unsigned_long_t

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format, time_local_at default_value)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` unsigned_long_t

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format, time_at default_value)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` unsigned_long_t

`*TYPECAST_UNUM_TEXT_T`

Convert text_t to unum_text_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unum_text_t : Provides operations to treat the underlying OctectString as Binary String or unsigned long value .)

`Returns:` unum_text_t

`*TYPECAST_URL_CATEGORY_T`

Convert text_t to url_category_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (url_category_t : Retrieves URL category and attributes from an URL)

`Returns:` url_category_t

`*TYPECAST_VENDOR_SPEC_APPID_AVP_T`

Convert text_t to vendor_spec_appid_avp_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (vendor_spec_appid_avp_t : Retrieves AVPs that are nested in the grouped AVP Vendor-Specific-Application-Id (code 260). The nested AVPs are:

- Vendor-Id
- Auth-Application-Id
- Acct-Application-Id

For example, to retrieve the Auth-Application-Id AVP from the Vendor-Specific-Application-Id AVP:

- For requests:
  DIAMETER.REQ.VENDOR_SPECIFIC_APPLICATION_ID.AUTH_APPLICATION_ID
- For responses:
  DIAMETER.RES.VENDOR_SPECIFIC_APPLICATION_ID.AUTH_APPLICATION_ID

)

`Returns:` vendor_spec_appid_avp_t

`*TYPECAST_VENDOR_SPEC_RADIUS_AVP_T`

Convert text_t to vendor_spec_radius_avp_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (vendor_spec_radius_avp_t :

- Vendor-Id

To retrieve the Vendor-Id from the Vendor-Specific AVP:

- RADIUS.REQ.VENDOR_SPECIFIC.VENDORID

)

`Returns:` vendor_spec_radius_avp_t

`*UNQUOTE` (`char` c)

If selected text is quoted by character c, Remove character c from beginning and end.

For example: Say the selected text is / "foo xyz bar " /. Then on executing UNQUOTE("") the selected text will become /foo xyz bar / This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

c- Character

`Returns:` text_t

`*URLSET_MATCHES_ANY` (text_t urlset_name)

Results in Boolean TRUE value if and only if the Text matches any of the patterns that are specified in the urlset named by the string argument. The matching is case-insensitive for domains, but case-sensitive for paths. For example:

- HTTP.REQ.HOST.APPEND(HTTP.REQ.URL).URLSET_MATCHES_ANY("urlset_forbidden") returns true when the combined domain and URL matches any pattern in the urlset whose name is "urlset_forbidden".

`Parameters` (expressions not allowed) `:`

urlset_name- urlset name

`Returns:` bool_at

`*URL_CATEGORIZE` (`uint` min_reputation, `uint` max_reputation)

Returns the URL category for the supplied URL with the given minimum and maximum reputation score. Where a score of 5 is most risky and 1 is least risky. If either score is set to 0, that bound would be ignored. By specifying the reputation scores, the function will returned the category with the highest score (most risky) based on the bounds. If there was an error getting the category or if the URL is invalid then it will result in an Undef error. For example: HTTP.REQ.HOST.APPEND(HTTP.REQ.URL).URL_CATEGORIZE(0, 0) returns value when the combined domain and URL is looked up for the URL category with the highest reputation score (most risky).

`Parameters` (expressions not allowed) `:`

min_reputation- Minimum reputation score of URL category

max_reputation- Maximum reputation score of URL category

`Returns:` url_category_t

`*URL_RESERVED_CHARS_SAFE`

Converts URL reserved characters to corresponding '%XX' values and retains the rest. This is a read only operation.

```
Based on RFC3986, following are considered URL unreserved characters:

    Alpha-numeric characters: a-z, A-Z, 0-9

    Hyphen and underscore: "-", "_"

    Dot: "."

    Tilde: "~"
```

The rest are converted to %XX encoding, 'XX' is the hex-based representation of the input character. If the requirement is to encode all but URL safe characters, please consider using HTTP_URL_SAFE method.

`Returns:` text_t

`*XML_DECRYPT` (text_t certKeyName)

Decrypt the selected content, which was encrypted using the W3C XML Encryption standard.

`Parameters` (expressions not allowed) `:`

certKeyName- identifies the certkey object containing the RSA private key to be used to decrypt the bulk encryption key in the selected EncryptedData element.

`Returns:` text_t

`*XML_ENCRYPT` (text_t certKeyName, encrypt_method_e method)

Encrypt the selected cleartext using the W3C XML Encryption standard.

`Parameters` (expressions not allowed) `:`

certKeyName- identifies the certkey object containing an X.509 certificate with the RSA public key to be used to encrypt the generated bulk encryption key. Note that the certKey object need not, and usually will not, include the associated RSA private key.

method- specifies the bulk encryption method (rc4, des3, aes128, aes192, or aes256) used to encrypt the content.

`Returns:` text_t

`*XML_ENCRYPT` (text_t certKeyName, encrypt_method_e method, `uint` flags)

Encrypt the selected cleartext using the W3C XML Encryption standard.

`Parameters` (expressions not allowed) `:`

certKeyName- identifies the certkey object containing an X.509 certificate with the RSA public key to be used to encrypt the generated bulk encryption key. Note that the certKey object need not, and usually will not, include the associated RSA private key.

method- specifies the bulk encryption method (rc4, des3, aes128, aes192, or aes256) used to encrypt the content.

flags- optional bit mask to specify optional elements in the EncryptedData element. These are hints to tell the receiver what private key to use to decrypt the bulk encryption key, providing information from the certKey's X.509 certificate.

- 1 - include a KeyName element with the certKeyName;
- 2 - include a KeyValue element with the RSA public key from the certificate;
- 4 - include an X509IssuerSerial element with the certificate serial number and issuer DN;
- 8 - include an X509SubjectName element with the certificate subject DN;
- 16 - include an X509Certificate element with the entire certificate;

`Returns:` text_t

`*XPATH_HTML_WITH_MARKUP` (`xpath_str` xpathex)

Applies an XPath expression to the DOM for an HTML document and returns the selected node-set or string, including markup like element tags. node-sets are converted to strings using the standard XPath string conversion routine. The selected portion of the document can be used as the target for rewrite actions.

Examples: HTTP.REQ.BODY(1000).XPATH_HTML_WITH_MARKUP(xp%//md/head/title%) returns the <title> element in the document's <head> This can be used in a rewrite action to replace or delete the <title> element.

`Parameters` (expressions not allowed) `:`

xpathex- XPath Expression

`Returns:` text_t

`*XPATH_HTML` (`xpath_bool` xpathex)

Applies an XPath expression to the DOM for an HTML document and a boolean value.

Examples: HTTP.RES.BODY(1000).XPATH_HTML(xp%boolean(/md/head/meta)%) returns true if the <meta> element exists as a child of <head> element.

`Parameters` (expressions not allowed) `:`

xpathex- XPath Expression

`Returns:` bool_at

`*XPATH_HTML` (`xpath_double` xpathex)

Applies an XPath expression to the DOM for an HTML document and a double value.

Examples: HTTP.RES.BODY(1000).XPATH_HTML(xp%number(//video/@height)%) returns the numeric value of the height attribute of the first <video> element.

`Parameters` (expressions not allowed) `:`

xpathex- XPath Expression

`Returns:` double_at

`*XPATH_HTML` (`xpath_str` xpathex)

Applies an XPath expression to the DOM for an HTML document and returns the selected node-set or string. node-sets are converted to strings using the standard XPath string conversion routine.

Examples: HTTP.REQ.BODY(1000).XPATH_HTML(xp%//img/@src%) returns the string value of the src attribute of the first

DNS_HEADER_T

This object provides operations for parsing the DNS header.

This topic lists the expressions that are provided by this class.

- `ANCOUNT`

  Returns the answer count in the DNS header.

`Returns:` num_at

- `ARCOUNT`

  Returns the additional record count in the DNS header.

`Returns:` num_at

- `FLAGS`

  Returns the value of DNS header flags

`Returns:` dns_flag_t

- `NSCOUNT`

  Returns the nameserver count in the DNS header.

`Returns:` num_at

- `OPCODE`

  Return the opcode in the DNS header.

`Returns:` dns_opcode_t

- `QDCOUNT`

  Returns the question count in the DNS header.

`Returns:` num_at

- `RCODE`

  Return the response code of the DNS question

`Returns:` dns_rcode_t

DNS_OPCODE_E

This object provides operations for parsing the DNS header opcode.

Enumerations

QUERY

IQUERY

STATUS

NOTIFY

UPDATE

This topic lists the expressions that are provided by this class.

`EQ` (dns_opcode_e m)

The result is Boolean TRUE if the input argument is equal to the DNS opcode type represented by this object.

`Parameters` (expressions not allowed) `:`

m- Dns opcode type

`Returns:` bool_at

`NE` (dns_opcode_e m)

The result is Boolean FALSE if the input argument is equal to the DNS opcode type represented by this object.

`Parameters` (expressions not allowed) `:`

m- Dns opcode type

`Returns:` bool_at

DNS_OPCODE_T

This object provides Num operations and Dns OpcodeType Enum operations.

This topic lists the expressions that are provided by this class.

`*Note` *: Expressions with the * symbol are inherited / promoted from dns_opcode_e num_at

`SET` (dns_opcode_e opcode)

Sets the specified opcode in the DNS header

`Parameters` (expressions not allowed) `:`

opcode- enum value

`Returns:` dns_opcode_t

`*TYPECAST_NUM_AT`

Convert dns_opcode_t to num_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (num_at : Number Value)

`Returns:` num_at

`*ABS`

Return the absolute value of the number.

`Returns:` num_at

`*ADD` (double_at i)

Return the Double Value after adding the argument to the current double value.

`Parameters``:`

i- Double

`Returns:` double_at

`*ADD` (ip_address_at i)

Return the Unsigned Long after adding the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*ADD` (unsigned_long_at i)

Return the Unsigned Long after adding the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*ADD` (num_at i)

Return the Number Value after adding the argument to the current number value.

`Parameters``:`

i- Number

`Returns:` num_at

`*ADD` (time_local_at i)

Return the Unsigned Long after adding the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*ADD` (time_at i)

Return the Unsigned Long after adding the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*APPEND` (text_t str)

Appends the given string to the string representation of the current number.

`Parameters``:`

str- the string to append.

`Returns:` text_t

`*AS_MICROSEC_STR`

Returns the current system time in the following format Format: Wday, day Month year hh:mm:ss.ffffff GMT ffffff represents microseconds Examples:

Mon, 05 Mar 2018 10:23:36.568419 GMT

`Returns:` text_t

`*AS_MILLISEC_STR`

Returns the current system time in the following format Format: Wday, day Month year hh:mm:ss.fff GMT fff represents milliseconds Examples:

Mon, 05 Mar 2018 10:23:36.568 GMT

`Returns:` text_t

`*AS_NANOSEC_STR`

Returns the current system time in the following format Format: Wday, day Month year hh:mm:ss.fffffffff GMT fffffffff represents nanoseconds Accuracy may be at larger granularity than nanosecond resolution. Examples:

Mon, 05 Mar 2018 10:23:36.568419567 GMT

`Returns:` text_t

`*BETWEEN` (double_at i, double_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (double_at i, ip_address_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (double_at i, unsigned_long_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (ip_address_at i, double_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (ip_address_at i, ip_address_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (ip_address_at i, unsigned_long_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (unsigned_long_at i, double_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (unsigned_long_at i, ip_address_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (unsigned_long_at i, unsigned_long_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (double_at i, num_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (ip_address_at i, num_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (unsigned_long_at i, num_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (double_at i, time_local_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (ip_address_at i, time_local_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (unsigned_long_at i, time_local_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (double_at i, time_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (ip_address_at i, time_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (unsigned_long_at i, time_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (num_at i, double_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (num_at i, ip_address_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (num_at i, unsigned_long_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (num_at i, num_at j)

Returns Boolean TRUE if the number value is greater than or equal to the Lower argument and the number value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (num_at i, time_local_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (num_at i, time_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (time_local_at i, double_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (time_local_at i, ip_address_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (time_local_at i, unsigned_long_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (time_local_at i, num_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (time_local_at i, time_local_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (time_local_at i, time_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (time_at i, double_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (time_at i, ip_address_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (time_at i, unsigned_long_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (time_at i, num_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (time_at i, time_local_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (time_at i, time_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BITAND` (ip_address_at i)

Return the Unsigned Long Value after bitwise ANDing the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*BITAND` (unsigned_long_at i)

Return the Unsigned Long Value after bitwise ANDing the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*BITAND` (num_at i)

Return the Number Value after bitwise ANDing the argument to the current number value.

`Parameters``:`

i- Number

`Returns:` num_at

`*BITAND` (time_local_at i)

Return the Unsigned Long Value after bitwise ANDing the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*BITAND` (time_at i)

Return the Unsigned Long Value after bitwise ANDing the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*BITNEG`

Return the Number Value after bitwise negating the current number value.

`Returns:` num_at

`*BITOR` (ip_address_at i)

Return the Unsigned Long Value after bitwise ORing the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*BITOR` (unsigned_long_at i)

Return the Unsigned Long Value after bitwise ORing the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*BITOR` (num_at i)

Return the Number Value after bitwise ORing the argument to the current number value.

`Parameters``:`

i- Number

`Returns:` num_at

`*BITOR` (time_local_at i)

Return the Unsigned Long Value after bitwise ORing the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*BITOR` (time_at i)

Return the Unsigned Long Value after bitwise ORing the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*BITXOR` (ip_address_at i)

Return the Unsigned Long Value after bitwise XORing the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*BITXOR` (unsigned_long_at i)

Return the Unsigned Long Value after bitwise XORing the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*BITXOR` (num_at i)

Return the Number Value after bitwise XORing the argument to the current number value.

`Parameters``:`

i- Number

`Returns:` num_at

`*BITXOR` (time_local_at i)

Return the Unsigned Long Value after bitwise XORing the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*BITXOR` (time_at i)

Return the Unsigned Long Value after bitwise XORing the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*DIV` (double_at i)

Return the Double Value after dividing the current double value by the argument.

`Parameters``:`

i- Double

`Returns:` double_at

`*DIV` (ip_address_at i)

Return the Unsigned Long Value after dividing the current unsigned long value by the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*DIV` (unsigned_long_at i)

Return the Unsigned Long Value after dividing the current unsigned long value by the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*DIV` (num_at i)

Return the Number Value after dividing the current number value by the argument.

`Parameters``:`

i- Number

`Returns:` num_at

`*DIV` (time_local_at i)

Return the Unsigned Long Value after dividing the current unsigned long value by the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*DIV` (time_at i)

Return the Unsigned Long Value after dividing the current unsigned long value by the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*EQ` (dns_opcode_e m)

The result is Boolean TRUE if the input argument is equal to the DNS opcode type represented by this object.

`Parameters` (expressions not allowed) `:`

m- Dns opcode type

`Returns:` bool_at

`*EQ` (double_at i)

Returns Boolean TRUE if the double value is equal to the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`*EQ` (ip_address_at i)

Returns Boolean TRUE if the unsigned long is equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*EQ` (unsigned_long_at i)

Returns Boolean TRUE if the unsigned long is equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*EQ` (num_at i)

Returns Boolean TRUE if the number value is equal to the argument.

`Parameters``:`

i- Number

`Returns:` bool_at

`*EQ` (time_local_at i)

Returns Boolean TRUE if the unsigned long is equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*EQ` (time_at i)

Returns Boolean TRUE if the unsigned long is equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*GE` (double_at i)

Returns Boolean TRUE if the double value is greater than or equal to the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`*GE` (ip_address_at i)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*GE` (unsigned_long_at i)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*GE` (num_at i)

Returns Boolean TRUE if the number value is greater than or equal to the argument.

`Parameters``:`

i- Number

`Returns:` bool_at

`*GE` (time_local_at i)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*GE` (time_at i)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*GT` (double_at i)

Returns Boolean TRUE if the double value is greater than the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`*GT` (ip_address_at i)

Returns Boolean TRUE if the unsigned long value is greater than the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*GT` (unsigned_long_at i)

Returns Boolean TRUE if the unsigned long value is greater than the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*GT` (num_at i)

Returns Boolean TRUE if the number value is greater than the argument.

`Parameters``:`

i- Number

`Returns:` bool_at

`*GT` (time_local_at i)

Returns Boolean TRUE if the unsigned long value is greater than the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*GT` (time_at i)

Returns Boolean TRUE if the unsigned long value is greater than the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*LE` (double_at i)

Returns Boolean TRUE if the double value is lesser than or equal to the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`*LE` (ip_address_at i)

Returns Boolean TRUE if the unsigned long value is lesser than or equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*LE` (unsigned_long_at i)

Returns Boolean TRUE if the unsigned long value is lesser than or equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*LE` (num_at i)

Returns Boolean TRUE if the number value is lesser than or equal to the argument.

`Parameters``:`

i- Number

`Returns:` bool_at

`*LE` (time_local_at i)

Returns Boolean TRUE if the unsigned long value is lesser than or equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*LE` (time_at i)

Returns Boolean TRUE if the unsigned long value is lesser than or equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*LSHIFT` (`uint` i)

Return the Number Value after bitwise left shifting the current number value by the argument number of bits. Note that the number of bits shifted is i modulo 32. For example, let HTTP.REQ.URL.LENGTH be 4. Then, HTTP.REQ.URL.LENGTH.LSHIFT(1) = HTTP.REQ.URL.LENGTH.LSHIFT(33) = 8, since 33 on division by 32 yields a remainder of 1.

`Parameters``:`

i- Left Shift Length

`Returns:` num_at

`*LT` (double_at i)

Returns Boolean TRUE if the double value is lesser than the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`*LT` (ip_address_at i)

Returns Boolean TRUE if the unsigned long value is lesser than the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*LT` (unsigned_long_at i)

Returns Boolean TRUE if the unsigned long value is lesser than the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*LT` (num_at i)

Returns Boolean TRUE if the number value is lesser than the argument.

`Parameters``:`

i- Number

`Returns:` bool_at

`*LT` (time_local_at i)

Returns Boolean TRUE if the unsigned long value is lesser than the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*LT` (time_at i)

Returns Boolean TRUE if the unsigned long value is lesser than the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*MAX` (double_at i)

Return the maximum double value after comparing the argument with the current double value.

`Parameters``:`

i- Double

`Returns:` double_at

`*MAX` (ip_address_at i)

Return the maximum unsigned long value after comparing the argument value to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MAX` (unsigned_long_at i)

Return the maximum unsigned long value after comparing the argument value to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MAX` (num_at i)

Return the maximum value after comparing the argument with the current number value.

`Parameters``:`

i- Number

`Returns:` num_at

`*MAX` (time_local_at i)

Return the maximum unsigned long value after comparing the argument value to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MAX` (time_at i)

Return the maximum unsigned long value after comparing the argument value to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MIN` (double_at i)

Return the minimum double value after comparing the argument with the current double value.

`Parameters``:`

i- Double

`Returns:` double_at

`*MIN` (ip_address_at i)

Return the minimum unsigned long value after comparing the argument value to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MIN` (unsigned_long_at i)

Return the minimum unsigned long value after comparing the argument value to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MIN` (num_at i)

Return the minimum value after comparing the argument with the current number value.

`Parameters``:`

i- Number

`Returns:` num_at

`*MIN` (time_local_at i)

Return the minimum unsigned long value after comparing the argument value to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MIN` (time_at i)

Return the minimum unsigned long value after comparing the argument value to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MOD` (ip_address_at i)

Return the Unsigned Long Value that is the renaminder after dividing the current unsigned long value by the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MOD` (unsigned_long_at i)

Return the Unsigned Long Value that is the renaminder after dividing the current unsigned long value by the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MOD` (num_at i)

Return the Number Value that is the renaminder after dividing the current number value by the argument.

`Parameters``:`

i- Number

`Returns:` num_at

`*MOD` (time_local_at i)

Return the Unsigned Long Value that is the renaminder after dividing the current unsigned long value by the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MOD` (time_at i)

Return the Unsigned Long Value that is the renaminder after dividing the current unsigned long value by the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MUL` (double_at i)

Return the Double Value after multiplying the argument to the current double value.

`Parameters``:`

i- Double

`Returns:` double_at

`*MUL` (ip_address_at i)

Return the Unsigned Long Value after multiplying the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MUL` (unsigned_long_at i)

Return the Unsigned Long Value after multiplying the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MUL` (num_at i)

Return the Number Value after multiplying the argument to the current number value.

`Parameters``:`

i- Number

`Returns:` num_at

`*MUL` (time_local_at i)

Return the Unsigned Long Value after multiplying the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MUL` (time_at i)

Return the Unsigned Long Value after multiplying the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*NEG`

Return the Number Value after negating the current number value.

`Returns:` num_at

`*NE` (dns_opcode_e m)

The result is Boolean FALSE if the input argument is equal to the DNS opcode type represented by this object.

`Parameters` (expressions not allowed) `:`

m- Dns opcode type

`Returns:` bool_at

`*NE` (double_at i)

Returns Boolean TRUE if the double value is not equal to the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`*NE` (ip_address_at i)

Returns Boolean TRUE if the unsigned long value is not equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*NE` (unsigned_long_at i)

Returns Boolean TRUE if the unsigned long value is not equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*NE` (num_at i)

Returns Boolean TRUE if the number value is not equal to the argument.

`Parameters``:`

i- Number

`Returns:` bool_at

`*NE` (time_local_at i)

Returns Boolean TRUE if the unsigned long value is not equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*NE` (time_at i)

Returns Boolean TRUE if the unsigned long value is not equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*RSHIFT` (`uint` i)

Return the Number Value after bitwise right shifting the current number value by the argument number of bits. Note that the number of bits shifted is i modulo 32. For example, let HTTP.REQ.URL.LENGTH be 4. Then, HTTP.REQ.URL.LENGTH.RSHIFT(1) = HTTP.REQ.URL.LENGTH.RSHIFT(33) = 2, since 33 on division by 32 yields a remainder of 1.

`Parameters``:`

i- Right Shift Length

`Returns:` num_at

`*SIGNED16_STRING` (endian_e endianness)

Create a signed 16-bit binary string from the number.

`Parameters` (expressions not allowed) `:`

endianness- Select little or big endian

`Returns:` text_t

`*SIGNED32_STRING` (endian_e endianness)

Create a signed 32-bit binary string from the number.

`Parameters` (expressions not allowed) `:`

endianness- Select little or big endian

`Returns:` text_t

`*SIGNED8_STRING`

Create a signed 8-bit binary string from the number.

`Returns:` text_t

`*SUB` (double_at i)

Return the Double Value after subtracting the argument from the current double value.

`Parameters``:`

i- Double

`Returns:` double_at

`*SUB` (ip_address_at i)

Return the Unsigned Long Value after subtracting the argument from the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*SUB` (unsigned_long_at i)

Return the Unsigned Long Value after subtracting the argument from the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*SUB` (num_at i)

Return the Number Value after subtracting the argument from the current number value.

`Parameters``:`

i- Number

`Returns:` num_at

`*SUB` (time_local_at i)

Return the Unsigned Long Value after subtracting the argument from the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*SUB` (time_at i)

Return the Unsigned Long Value after subtracting the argument from the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*TYPECAST_DOUBLE_AT`

Typecast the Number Value to a Double value.

`Returns:` double_at

`*TYPECAST_IP_ADDRESS_AT`

Typecast the Number Value to an IP Address value.

`Returns:` ip_address_at

`*TYPECAST_TEXT_T`

Typecast the Number Value to its string representation.

`Returns:` text_t

`*TYPECAST_TIME_AT`

Typecast the Number Value to a Time value.

`Returns:` time_at

`*TYPECAST_TIME_LOCAL_AT`

Typecast the Number Value to a local time value.

`Returns:` time_local_at

`*TYPECAST_UNSIGNED_LONG_AT`

Typecast the Number Value to a Unsigned Long value.

`Returns:` unsigned_long_at

`*UNSIGNED16_STRING` (endian_e endianness)

Create an unsigned 16-bit binary string from the number.

`Parameters` (expressions not allowed) `:`

endianness- Select little or big endian

`Returns:` text_t

`*UNSIGNED32_STRING` (endian_e endianness)

Create an unsigned 32-bit binary string from the number.

`Parameters` (expressions not allowed) `:`

endianness- Select little or big endian

`Returns:` text_t

`*UNSIGNED64_STRING` (endian_e endianness)

Create an unsigned 64-bit binary string from the number.

`Parameters` (expressions not allowed) `:`

endianness- Select little or big endian

`Returns:` text_t

`*UNSIGNED8_STRING`

Create an unsigned 8-bit binary string from the number.

`Returns:` text_t

`*WEEKDAY_STRING`

Given the numeric day of the week, e.g. SYS.TIME.WEEKDAY, return the long form of the string name for that day, e.g. 0 = "Sunday", 6 = "Saturday".

`Returns:` text_t

`*WEEKDAY_STRING_SHORT`

Given the numeric day of the week, e.g. SYS.TIME.WEEKDAY, return the short form of the string name for that day, e.g. 0 = "Sun", 6 = "Sat".

`Returns:` text_t

DNS_OPT_T

This object provides operations for parsing the DNS OPT record.

This topic lists the expressions that are provided by this class.

- `ECS`

  Returns EDNS client subnet option (if exists).

`Returns:` dns_ecs_t

- `ECS_EXISTS`

  Returns true if EDNS client subnet option is present in the OPT record.

`Returns:` bool_at

DNS_PROTOCOL_T

Models the DNS message types.

This topic lists the expressions that are provided by this class.

- `LENGTH`

  Returns the DNS packet length. In case of DNS-TCP, it includes 2 byte length field as well.

`Returns:` num_at

- `NEW_RESPONSE`

  Creates an empty DNS response based on request header.

`Returns:` text_t

`NEW_RESPONSE` (bool_at AA, bool_at TC, dns_rcode_e rcode)

Creates a new empty DNS response based on the given parameters.

`Parameters` (expressions not allowed) `:`

AA- Authoritative Answer flag

TC- Truncated flag

rcode- Retrun Code

`Returns:` text_t

`NEW_RRSET_AAAA` (text_t iplist, `uint` ttl)

Creates a new RR set with the given ipv6 address and ttl parameters.

`Parameters` (expressions not allowed) `:`

iplist- Comma separated IPv6 address list

ttl- Time To Live

`Returns:` text_t

`NEW_RRSET_A` (text_t iplist, `uint` ttl)

Creates a new RR set with the given ipv4 address and ttl parameters.

`Parameters` (expressions not allowed) `:`

iplist- Comma separated IP address list

ttl- Time To Live

`Returns:` text_t

- `REQ`

  Operates on DNS Request.

`Returns:` dns_req_t

- `RES`

  Operates on DNS Response.

`Returns:` dns_res_t

- `RR`

  Operates on DNS Resource Record(RR).

`Returns:` dns_rr_t

DNS_QUESTION_T

This object provides operations for parsing the DNS question.

This topic lists the expressions that are provided by this class.

- `DOMAIN`

  Returns domain name. Sets the text mode to case insensitive.

`Returns:` dns_domainname_t

- `TYPE`

  Returns DNS Record type.

`Returns:` dns_type_t

DNS_RCODE_E

This object provides operations for parsing the DNS header response code.

Enumerations

NOERROR

FORMERR

SERVFAIL

NXDOMAIN

NOTIMP

REFUSED

This topic lists the expressions that are provided by this class.

`EQ` (dns_rcode_e m)

The result is Boolean TRUE if the input argument is equal to the DNS response code represented by this object.

`Parameters` (expressions not allowed) `:`

m- DNS response code

`Returns:` bool_at

`NE` (dns_rcode_e m)

The result is Boolean TRUE if the input argument is not equal to the DNS response code represented by this object.

`Parameters` (expressions not allowed) `:`

m- DNS response code

`Returns:` bool_at

DNS_RCODE_T

This object provides Num operations and Dns RcodeType Enum operations.

This topic lists the expressions that are provided by this class.

`*Note` *: Expressions with the * symbol are inherited / promoted from dns_rcode_e num_at

`SET` (dns_rcode_e rcode)

Sets the specified rcode in the DNS header

`Parameters` (expressions not allowed) `:`

rcode- enum value

`Returns:` dns_rcode_t

`*TYPECAST_NUM_AT`

Convert dns_rcode_t to num_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (num_at : Number Value)

`Returns:` num_at

`*ABS`

Return the absolute value of the number.

`Returns:` num_at

`*ADD` (double_at i)

Return the Double Value after adding the argument to the current double value.

`Parameters``:`

i- Double

`Returns:` double_at

`*ADD` (ip_address_at i)

Return the Unsigned Long after adding the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*ADD` (unsigned_long_at i)

Return the Unsigned Long after adding the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*ADD` (num_at i)

Return the Number Value after adding the argument to the current number value.

`Parameters``:`

i- Number

`Returns:` num_at

`*ADD` (time_local_at i)

Return the Unsigned Long after adding the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*ADD` (time_at i)

Return the Unsigned Long after adding the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*APPEND` (text_t str)

Appends the given string to the string representation of the current number.

`Parameters``:`

str- the string to append.

`Returns:` text_t

`*AS_MICROSEC_STR`

Returns the current system time in the following format Format: Wday, day Month year hh:mm:ss.ffffff GMT ffffff represents microseconds Examples:

Mon, 05 Mar 2018 10:23:36.568419 GMT

`Returns:` text_t

`*AS_MILLISEC_STR`

Returns the current system time in the following format Format: Wday, day Month year hh:mm:ss.fff GMT fff represents milliseconds Examples:

Mon, 05 Mar 2018 10:23:36.568 GMT

`Returns:` text_t

`*AS_NANOSEC_STR`

Returns the current system time in the following format Format: Wday, day Month year hh:mm:ss.fffffffff GMT fffffffff represents nanoseconds Accuracy may be at larger granularity than nanosecond resolution. Examples:

Mon, 05 Mar 2018 10:23:36.568419567 GMT

`Returns:` text_t

`*BETWEEN` (double_at i, double_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (double_at i, ip_address_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (double_at i, unsigned_long_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (ip_address_at i, double_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (ip_address_at i, ip_address_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (ip_address_at i, unsigned_long_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (unsigned_long_at i, double_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (unsigned_long_at i, ip_address_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (unsigned_long_at i, unsigned_long_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (double_at i, num_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (ip_address_at i, num_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (unsigned_long_at i, num_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (double_at i, time_local_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (ip_address_at i, time_local_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (unsigned_long_at i, time_local_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (double_at i, time_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (ip_address_at i, time_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (unsigned_long_at i, time_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (num_at i, double_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (num_at i, ip_address_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (num_at i, unsigned_long_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (num_at i, num_at j)

Returns Boolean TRUE if the number value is greater than or equal to the Lower argument and the number value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (num_at i, time_local_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (num_at i, time_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (time_local_at i, double_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (time_local_at i, ip_address_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (time_local_at i, unsigned_long_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (time_local_at i, num_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (time_local_at i, time_local_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (time_local_at i, time_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (time_at i, double_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (time_at i, ip_address_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (time_at i, unsigned_long_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (time_at i, num_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (time_at i, time_local_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (time_at i, time_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BITAND` (ip_address_at i)

Return the Unsigned Long Value after bitwise ANDing the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*BITAND` (unsigned_long_at i)

Return the Unsigned Long Value after bitwise ANDing the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*BITAND` (num_at i)

Return the Number Value after bitwise ANDing the argument to the current number value.

`Parameters``:`

i- Number

`Returns:` num_at

`*BITAND` (time_local_at i)

Return the Unsigned Long Value after bitwise ANDing the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*BITAND` (time_at i)

Return the Unsigned Long Value after bitwise ANDing the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*BITNEG`

Return the Number Value after bitwise negating the current number value.

`Returns:` num_at

`*BITOR` (ip_address_at i)

Return the Unsigned Long Value after bitwise ORing the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*BITOR` (unsigned_long_at i)

Return the Unsigned Long Value after bitwise ORing the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*BITOR` (num_at i)

Return the Number Value after bitwise ORing the argument to the current number value.

`Parameters``:`

i- Number

`Returns:` num_at

`*BITOR` (time_local_at i)

Return the Unsigned Long Value after bitwise ORing the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*BITOR` (time_at i)

Return the Unsigned Long Value after bitwise ORing the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*BITXOR` (ip_address_at i)

Return the Unsigned Long Value after bitwise XORing the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*BITXOR` (unsigned_long_at i)

Return the Unsigned Long Value after bitwise XORing the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*BITXOR` (num_at i)

Return the Number Value after bitwise XORing the argument to the current number value.

`Parameters``:`

i- Number

`Returns:` num_at

`*BITXOR` (time_local_at i)

Return the Unsigned Long Value after bitwise XORing the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*BITXOR` (time_at i)

Return the Unsigned Long Value after bitwise XORing the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*DIV` (double_at i)

Return the Double Value after dividing the current double value by the argument.

`Parameters``:`

i- Double

`Returns:` double_at

`*DIV` (ip_address_at i)

Return the Unsigned Long Value after dividing the current unsigned long value by the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*DIV` (unsigned_long_at i)

Return the Unsigned Long Value after dividing the current unsigned long value by the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*DIV` (num_at i)

Return the Number Value after dividing the current number value by the argument.

`Parameters``:`

i- Number

`Returns:` num_at

`*DIV` (time_local_at i)

Return the Unsigned Long Value after dividing the current unsigned long value by the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*DIV` (time_at i)

Return the Unsigned Long Value after dividing the current unsigned long value by the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*EQ` (dns_rcode_e m)

The result is Boolean TRUE if the input argument is equal to the DNS response code represented by this object.

`Parameters` (expressions not allowed) `:`

m- DNS response code

`Returns:` bool_at

`*EQ` (double_at i)

Returns Boolean TRUE if the double value is equal to the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`*EQ` (ip_address_at i)

Returns Boolean TRUE if the unsigned long is equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*EQ` (unsigned_long_at i)

Returns Boolean TRUE if the unsigned long is equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*EQ` (num_at i)

Returns Boolean TRUE if the number value is equal to the argument.

`Parameters``:`

i- Number

`Returns:` bool_at

`*EQ` (time_local_at i)

Returns Boolean TRUE if the unsigned long is equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*EQ` (time_at i)

Returns Boolean TRUE if the unsigned long is equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*GE` (double_at i)

Returns Boolean TRUE if the double value is greater than or equal to the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`*GE` (ip_address_at i)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*GE` (unsigned_long_at i)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*GE` (num_at i)

Returns Boolean TRUE if the number value is greater than or equal to the argument.

`Parameters``:`

i- Number

`Returns:` bool_at

`*GE` (time_local_at i)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*GE` (time_at i)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*GT` (double_at i)

Returns Boolean TRUE if the double value is greater than the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`*GT` (ip_address_at i)

Returns Boolean TRUE if the unsigned long value is greater than the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*GT` (unsigned_long_at i)

Returns Boolean TRUE if the unsigned long value is greater than the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*GT` (num_at i)

Returns Boolean TRUE if the number value is greater than the argument.

`Parameters``:`

i- Number

`Returns:` bool_at

`*GT` (time_local_at i)

Returns Boolean TRUE if the unsigned long value is greater than the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*GT` (time_at i)

Returns Boolean TRUE if the unsigned long value is greater than the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*LE` (double_at i)

Returns Boolean TRUE if the double value is lesser than or equal to the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`*LE` (ip_address_at i)

Returns Boolean TRUE if the unsigned long value is lesser than or equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*LE` (unsigned_long_at i)

Returns Boolean TRUE if the unsigned long value is lesser than or equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*LE` (num_at i)

Returns Boolean TRUE if the number value is lesser than or equal to the argument.

`Parameters``:`

i- Number

`Returns:` bool_at

`*LE` (time_local_at i)

Returns Boolean TRUE if the unsigned long value is lesser than or equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*LE` (time_at i)

Returns Boolean TRUE if the unsigned long value is lesser than or equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*LSHIFT` (`uint` i)

Return the Number Value after bitwise left shifting the current number value by the argument number of bits. Note that the number of bits shifted is i modulo 32. For example, let HTTP.REQ.URL.LENGTH be 4. Then, HTTP.REQ.URL.LENGTH.LSHIFT(1) = HTTP.REQ.URL.LENGTH.LSHIFT(33) = 8, since 33 on division by 32 yields a remainder of 1.

`Parameters``:`

i- Left Shift Length

`Returns:` num_at

`*LT` (double_at i)

Returns Boolean TRUE if the double value is lesser than the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`*LT` (ip_address_at i)

Returns Boolean TRUE if the unsigned long value is lesser than the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*LT` (unsigned_long_at i)

Returns Boolean TRUE if the unsigned long value is lesser than the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*LT` (num_at i)

Returns Boolean TRUE if the number value is lesser than the argument.

`Parameters``:`

i- Number

`Returns:` bool_at

`*LT` (time_local_at i)

Returns Boolean TRUE if the unsigned long value is lesser than the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*LT` (time_at i)

Returns Boolean TRUE if the unsigned long value is lesser than the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*MAX` (double_at i)

Return the maximum double value after comparing the argument with the current double value.

`Parameters``:`

i- Double

`Returns:` double_at

`*MAX` (ip_address_at i)

Return the maximum unsigned long value after comparing the argument value to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MAX` (unsigned_long_at i)

Return the maximum unsigned long value after comparing the argument value to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MAX` (num_at i)

Return the maximum value after comparing the argument with the current number value.

`Parameters``:`

i- Number

`Returns:` num_at

`*MAX` (time_local_at i)

Return the maximum unsigned long value after comparing the argument value to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MAX` (time_at i)

Return the maximum unsigned long value after comparing the argument value to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MIN` (double_at i)

Return the minimum double value after comparing the argument with the current double value.

`Parameters``:`

i- Double

`Returns:` double_at

`*MIN` (ip_address_at i)

Return the minimum unsigned long value after comparing the argument value to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MIN` (unsigned_long_at i)

Return the minimum unsigned long value after comparing the argument value to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MIN` (num_at i)

Return the minimum value after comparing the argument with the current number value.

`Parameters``:`

i- Number

`Returns:` num_at

`*MIN` (time_local_at i)

Return the minimum unsigned long value after comparing the argument value to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MIN` (time_at i)

Return the minimum unsigned long value after comparing the argument value to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MOD` (ip_address_at i)

Return the Unsigned Long Value that is the renaminder after dividing the current unsigned long value by the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MOD` (unsigned_long_at i)

Return the Unsigned Long Value that is the renaminder after dividing the current unsigned long value by the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MOD` (num_at i)

Return the Number Value that is the renaminder after dividing the current number value by the argument.

`Parameters``:`

i- Number

`Returns:` num_at

`*MOD` (time_local_at i)

Return the Unsigned Long Value that is the renaminder after dividing the current unsigned long value by the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MOD` (time_at i)

Return the Unsigned Long Value that is the renaminder after dividing the current unsigned long value by the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MUL` (double_at i)

Return the Double Value after multiplying the argument to the current double value.

`Parameters``:`

i- Double

`Returns:` double_at

`*MUL` (ip_address_at i)

Return the Unsigned Long Value after multiplying the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MUL` (unsigned_long_at i)

Return the Unsigned Long Value after multiplying the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MUL` (num_at i)

Return the Number Value after multiplying the argument to the current number value.

`Parameters``:`

i- Number

`Returns:` num_at

`*MUL` (time_local_at i)

Return the Unsigned Long Value after multiplying the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MUL` (time_at i)

Return the Unsigned Long Value after multiplying the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*NEG`

Return the Number Value after negating the current number value.

`Returns:` num_at

`*NE` (dns_rcode_e m)

The result is Boolean TRUE if the input argument is not equal to the DNS response code represented by this object.

`Parameters` (expressions not allowed) `:`

m- DNS response code

`Returns:` bool_at

`*NE` (double_at i)

Returns Boolean TRUE if the double value is not equal to the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`*NE` (ip_address_at i)

Returns Boolean TRUE if the unsigned long value is not equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*NE` (unsigned_long_at i)

Returns Boolean TRUE if the unsigned long value is not equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*NE` (num_at i)

Returns Boolean TRUE if the number value is not equal to the argument.

`Parameters``:`

i- Number

`Returns:` bool_at

`*NE` (time_local_at i)

Returns Boolean TRUE if the unsigned long value is not equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*NE` (time_at i)

Returns Boolean TRUE if the unsigned long value is not equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*RSHIFT` (`uint` i)

Return the Number Value after bitwise right shifting the current number value by the argument number of bits. Note that the number of bits shifted is i modulo 32. For example, let HTTP.REQ.URL.LENGTH be 4. Then, HTTP.REQ.URL.LENGTH.RSHIFT(1) = HTTP.REQ.URL.LENGTH.RSHIFT(33) = 2, since 33 on division by 32 yields a remainder of 1.

`Parameters``:`

i- Right Shift Length

`Returns:` num_at

`*SIGNED16_STRING` (endian_e endianness)

Create a signed 16-bit binary string from the number.

`Parameters` (expressions not allowed) `:`

endianness- Select little or big endian

`Returns:` text_t

`*SIGNED32_STRING` (endian_e endianness)

Create a signed 32-bit binary string from the number.

`Parameters` (expressions not allowed) `:`

endianness- Select little or big endian

`Returns:` text_t

`*SIGNED8_STRING`

Create a signed 8-bit binary string from the number.

`Returns:` text_t

`*SUB` (double_at i)

Return the Double Value after subtracting the argument from the current double value.

`Parameters``:`

i- Double

`Returns:` double_at

`*SUB` (ip_address_at i)

Return the Unsigned Long Value after subtracting the argument from the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*SUB` (unsigned_long_at i)

Return the Unsigned Long Value after subtracting the argument from the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*SUB` (num_at i)

Return the Number Value after subtracting the argument from the current number value.

`Parameters``:`

i- Number

`Returns:` num_at

`*SUB` (time_local_at i)

Return the Unsigned Long Value after subtracting the argument from the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*SUB` (time_at i)

Return the Unsigned Long Value after subtracting the argument from the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*TYPECAST_DOUBLE_AT`

Typecast the Number Value to a Double value.

`Returns:` double_at

`*TYPECAST_IP_ADDRESS_AT`

Typecast the Number Value to an IP Address value.

`Returns:` ip_address_at

`*TYPECAST_TEXT_T`

Typecast the Number Value to its string representation.

`Returns:` text_t

`*TYPECAST_TIME_AT`

Typecast the Number Value to a Time value.

`Returns:` time_at

`*TYPECAST_TIME_LOCAL_AT`

Typecast the Number Value to a local time value.

`Returns:` time_local_at

`*TYPECAST_UNSIGNED_LONG_AT`

Typecast the Number Value to a Unsigned Long value.

`Returns:` unsigned_long_at

`*UNSIGNED16_STRING` (endian_e endianness)

Create an unsigned 16-bit binary string from the number.

`Parameters` (expressions not allowed) `:`

endianness- Select little or big endian

`Returns:` text_t

`*UNSIGNED32_STRING` (endian_e endianness)

Create an unsigned 32-bit binary string from the number.

`Parameters` (expressions not allowed) `:`

endianness- Select little or big endian

`Returns:` text_t

`*UNSIGNED64_STRING` (endian_e endianness)

Create an unsigned 64-bit binary string from the number.

`Parameters` (expressions not allowed) `:`

endianness- Select little or big endian

`Returns:` text_t

`*UNSIGNED8_STRING`

Create an unsigned 8-bit binary string from the number.

`Returns:` text_t

`*WEEKDAY_STRING`

Given the numeric day of the week, e.g. SYS.TIME.WEEKDAY, return the long form of the string name for that day, e.g. 0 = "Sunday", 6 = "Saturday".

`Returns:` text_t

`*WEEKDAY_STRING_SHORT`

Given the numeric day of the week, e.g. SYS.TIME.WEEKDAY, return the short form of the string name for that day, e.g. 0 = "Sun", 6 = "Sat".

`Returns:` text_t

DNS_RDATA_T

This object provides operations for interpreting the data present in RDATA section of DNS Resource Record (RR).

This topic lists the expressions that are provided by this class.

- `IP`

  Returns the IP address from an A record.

`Returns:` ip_address_at

- `IPV6`

  Returns the IPV6 address from an AAAA record.

`Returns:` ipv6_address_at

DNS_REQ_T

Operates on DNS Request. This is the starting point for accessing request side dns packet

This topic lists the expressions that are provided by this class.

- `HEADER`

  Returns DNS request header information.

`Returns:` dns_header_t

- `OPT`

  Returns the OPT record (if it exists) in the additional section.

`Returns:` dns_opt_t

- `QUESTION`

  Returns DNS question which has domain and resource record information.

`Returns:` dns_question_t

- `TRANSPORT`

  Returns DNS transport layer protocol type.

`Returns:` dns_transport_e

DNS_RES_T

Operates on DNS Response. This is the starting point for accessing response side dns packet

This topic lists the expressions that are provided by this class.

- `HEADER`

  Returns DNS response header which contains response code information.

`Returns:` dns_header_t

- `OPT`

  Returns the OPT record (if it exists) in the additional section.

`Returns:` dns_opt_t

- `QUESTION`

  Returns DNS question which has domain and resource record information.

`Returns:` dns_question_t

- `TRANSPORT`

  Returns DNS transport layer protocol type.

`Returns:` dns_transport_e

DNS_RR_T

This object provides operations for parsing the DNS Resource Record (RR).

This topic lists the expressions that are provided by this class.

- `RDATA`

  Returns RDATA in the RR. Sets the text mode to case insensitive.

`Returns:` dns_rdata_t

- `TYPE`

  Returns The DNS Record type.

`Returns:` dns_type_e

DNS_TRANSPORT_E

This object provides DNS Transport information

Enumerations

TCP

UDP

This topic lists the expressions that are provided by this class.

`EQ` (dns_transport_e m)

The result is Boolean TRUE if the input argument is equal to the DNS transport protocol type represented by this object.

`Parameters` (expressions not allowed) `:`

m- Dns transport protocol type

`Returns:` bool_at

`NE` (dns_transport_e m)

The result is Boolean FALSE if the input argument is equal to the DNS transport protocol type represented by this object.

`Parameters` (expressions not allowed) `:`

m- Dns transport protocol type

`Returns:` bool_at

DNS_TYPE_E

This object provides operations for parsing the DNS resourse record type.

Enumerations

A

AAAA

ANY

CNAME

PTR

MX

NS

SRV

SOA

TXT

NAPTR

This topic lists the expressions that are provided by this class.

`EQ` (dns_type_e m)

The result is Boolean TRUE if the input argument is equal to the DNS record type represented by this object.

`Parameters` (expressions not allowed) `:`

m- Dns record type

`Returns:` bool_at

`NE` (dns_type_e m)

The result is Boolean FALSE if the input argument is equal to the DNS record type represented by this object.

`Parameters` (expressions not allowed) `:`

m- Dns record type

`Returns:` bool_at

DNS_TYPE_T

This object provides Num operations and DnsType Enum operations on the DNS Record Type.

This topic lists the expressions that are provided by this class.

`*Note` *: Expressions with the * symbol are inherited / promoted from dns_type_e num_at

- `TYPECAST_NUM_AT`

  Convert dns_type_t to num_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (num_at : Number Value)

`Returns:` num_at

`*ABS`

Return the absolute value of the number.

`Returns:` num_at

`*ADD` (double_at i)

Return the Double Value after adding the argument to the current double value.

`Parameters``:`

i- Double

`Returns:` double_at

`*ADD` (ip_address_at i)

Return the Unsigned Long after adding the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*ADD` (unsigned_long_at i)

Return the Unsigned Long after adding the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*ADD` (num_at i)

Return the Number Value after adding the argument to the current number value.

`Parameters``:`

i- Number

`Returns:` num_at

`*ADD` (time_local_at i)

Return the Unsigned Long after adding the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*ADD` (time_at i)

Return the Unsigned Long after adding the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*APPEND` (text_t str)

Appends the given string to the string representation of the current number.

`Parameters``:`

str- the string to append.

`Returns:` text_t

`*AS_MICROSEC_STR`

Returns the current system time in the following format Format: Wday, day Month year hh:mm:ss.ffffff GMT ffffff represents microseconds Examples:

Mon, 05 Mar 2018 10:23:36.568419 GMT

`Returns:` text_t

`*AS_MILLISEC_STR`

Returns the current system time in the following format Format: Wday, day Month year hh:mm:ss.fff GMT fff represents milliseconds Examples:

Mon, 05 Mar 2018 10:23:36.568 GMT

`Returns:` text_t

`*AS_NANOSEC_STR`

Returns the current system time in the following format Format: Wday, day Month year hh:mm:ss.fffffffff GMT fffffffff represents nanoseconds Accuracy may be at larger granularity than nanosecond resolution. Examples:

Mon, 05 Mar 2018 10:23:36.568419567 GMT

`Returns:` text_t

`*BETWEEN` (double_at i, double_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (double_at i, ip_address_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (double_at i, unsigned_long_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (ip_address_at i, double_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (ip_address_at i, ip_address_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (ip_address_at i, unsigned_long_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (unsigned_long_at i, double_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (unsigned_long_at i, ip_address_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (unsigned_long_at i, unsigned_long_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (double_at i, num_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (ip_address_at i, num_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (unsigned_long_at i, num_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (double_at i, time_local_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (ip_address_at i, time_local_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (unsigned_long_at i, time_local_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (double_at i, time_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (ip_address_at i, time_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (unsigned_long_at i, time_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (num_at i, double_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (num_at i, ip_address_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (num_at i, unsigned_long_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (num_at i, num_at j)

Returns Boolean TRUE if the number value is greater than or equal to the Lower argument and the number value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (num_at i, time_local_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (num_at i, time_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (time_local_at i, double_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (time_local_at i, ip_address_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (time_local_at i, unsigned_long_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (time_local_at i, num_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (time_local_at i, time_local_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (time_local_at i, time_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (time_at i, double_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (time_at i, ip_address_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (time_at i, unsigned_long_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (time_at i, num_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (time_at i, time_local_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (time_at i, time_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BITAND` (ip_address_at i)

Return the Unsigned Long Value after bitwise ANDing the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*BITAND` (unsigned_long_at i)

Return the Unsigned Long Value after bitwise ANDing the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*BITAND` (num_at i)

Return the Number Value after bitwise ANDing the argument to the current number value.

`Parameters``:`

i- Number

`Returns:` num_at

`*BITAND` (time_local_at i)

Return the Unsigned Long Value after bitwise ANDing the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*BITAND` (time_at i)

Return the Unsigned Long Value after bitwise ANDing the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*BITNEG`

Return the Number Value after bitwise negating the current number value.

`Returns:` num_at

`*BITOR` (ip_address_at i)

Return the Unsigned Long Value after bitwise ORing the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*BITOR` (unsigned_long_at i)

Return the Unsigned Long Value after bitwise ORing the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*BITOR` (num_at i)

Return the Number Value after bitwise ORing the argument to the current number value.

`Parameters``:`

i- Number

`Returns:` num_at

`*BITOR` (time_local_at i)

Return the Unsigned Long Value after bitwise ORing the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*BITOR` (time_at i)

Return the Unsigned Long Value after bitwise ORing the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*BITXOR` (ip_address_at i)

Return the Unsigned Long Value after bitwise XORing the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*BITXOR` (unsigned_long_at i)

Return the Unsigned Long Value after bitwise XORing the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*BITXOR` (num_at i)

Return the Number Value after bitwise XORing the argument to the current number value.

`Parameters``:`

i- Number

`Returns:` num_at

`*BITXOR` (time_local_at i)

Return the Unsigned Long Value after bitwise XORing the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*BITXOR` (time_at i)

Return the Unsigned Long Value after bitwise XORing the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*DIV` (double_at i)

Return the Double Value after dividing the current double value by the argument.

`Parameters``:`

i- Double

`Returns:` double_at

`*DIV` (ip_address_at i)

Return the Unsigned Long Value after dividing the current unsigned long value by the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*DIV` (unsigned_long_at i)

Return the Unsigned Long Value after dividing the current unsigned long value by the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*DIV` (num_at i)

Return the Number Value after dividing the current number value by the argument.

`Parameters``:`

i- Number

`Returns:` num_at

`*DIV` (time_local_at i)

Return the Unsigned Long Value after dividing the current unsigned long value by the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*DIV` (time_at i)

Return the Unsigned Long Value after dividing the current unsigned long value by the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*EQ` (dns_type_e m)

The result is Boolean TRUE if the input argument is equal to the DNS record type represented by this object.

`Parameters` (expressions not allowed)`:`

m- Dns record type

`Returns:` bool_at

`*EQ` (double_at i)

Returns Boolean TRUE if the double value is equal to the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`*EQ` (ip_address_at i)

Returns Boolean TRUE if the unsigned long is equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*EQ` (unsigned_long_at i)

Returns Boolean TRUE if the unsigned long is equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*EQ` (num_at i)

Returns Boolean TRUE if the number value is equal to the argument.

`Parameters``:`

i- Number

`Returns:` bool_at

`*EQ` (time_local_at i)

Returns Boolean TRUE if the unsigned long is equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*EQ` (time_at i)

Returns Boolean TRUE if the unsigned long is equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*GE` (double_at i)

Returns Boolean TRUE if the double value is greater than or equal to the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`*GE` (ip_address_at i)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*GE` (unsigned_long_at i)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*GE` (num_at i)

Returns Boolean TRUE if the number value is greater than or equal to the argument.

`Parameters``:`

i- Number

`Returns:` bool_at

`*GE` (time_local_at i)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*GE` (time_at i)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*GT` (double_at i)

Returns Boolean TRUE if the double value is greater than the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`*GT` (ip_address_at i)

Returns Boolean TRUE if the unsigned long value is greater than the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*GT` (unsigned_long_at i)

Returns Boolean TRUE if the unsigned long value is greater than the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*GT` (num_at i)

Returns Boolean TRUE if the number value is greater than the argument.

`Parameters``:`

i- Number

`Returns:` bool_at

`*GT` (time_local_at i)

Returns Boolean TRUE if the unsigned long value is greater than the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*GT` (time_at i)

Returns Boolean TRUE if the unsigned long value is greater than the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*LE` (double_at i)

Returns Boolean TRUE if the double value is lesser than or equal to the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`*LE` (ip_address_at i)

Returns Boolean TRUE if the unsigned long value is lesser than or equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*LE` (unsigned_long_at i)

Returns Boolean TRUE if the unsigned long value is lesser than or equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*LE` (num_at i)

Returns Boolean TRUE if the number value is lesser than or equal to the argument.

`Parameters``:`

i- Number

`Returns:` bool_at

`*LE` (time_local_at i)

Returns Boolean TRUE if the unsigned long value is lesser than or equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*LE` (time_at i)

Returns Boolean TRUE if the unsigned long value is lesser than or equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*LSHIFT` (`uint` i)

Return the Number Value after bitwise left shifting the current number value by the argument number of bits. Note that the number of bits shifted is i modulo 32. For example, let HTTP.REQ.URL.LENGTH be 4. Then, HTTP.REQ.URL.LENGTH.LSHIFT(1) = HTTP.REQ.URL.LENGTH.LSHIFT(33) = 8, since 33 on division by 32 yields a remainder of 1.

`Parameters``:`

i- Left Shift Length

`Returns:` num_at

`*LT` (double_at i)

Returns Boolean TRUE if the double value is lesser than the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`*LT` (ip_address_at i)

Returns Boolean TRUE if the unsigned long value is lesser than the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*LT` (unsigned_long_at i)

Returns Boolean TRUE if the unsigned long value is lesser than the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*LT` (num_at i)

Returns Boolean TRUE if the number value is lesser than the argument.

`Parameters``:`

i- Number

`Returns:` bool_at

`*LT` (time_local_at i)

Returns Boolean TRUE if the unsigned long value is lesser than the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*LT` (time_at i)

Returns Boolean TRUE if the unsigned long value is lesser than the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*MAX` (double_at i)

Return the maximum double value after comparing the argument with the current double value.

`Parameters``:`

i- Double

`Returns:` double_at

`*MAX` (ip_address_at i)

Return the maximum unsigned long value after comparing the argument value to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MAX` (unsigned_long_at i)

Return the maximum unsigned long value after comparing the argument value to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MAX` (num_at i)

Return the maximum value after comparing the argument with the current number value.

`Parameters``:`

i- Number

`Returns:` num_at

`*MAX` (time_local_at i)

Return the maximum unsigned long value after comparing the argument value to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MAX` (time_at i)

Return the maximum unsigned long value after comparing the argument value to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MIN` (double_at i)

Return the minimum double value after comparing the argument with the current double value.

`Parameters``:`

i- Double

`Returns:` double_at

`*MIN` (ip_address_at i)

Return the minimum unsigned long value after comparing the argument value to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MIN` (unsigned_long_at i)

Return the minimum unsigned long value after comparing the argument value to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MIN` (num_at i)

Return the minimum value after comparing the argument with the current number value.

`Parameters``:`

i- Number

`Returns:` num_at

`*MIN` (time_local_at i)

Return the minimum unsigned long value after comparing the argument value to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MIN` (time_at i)

Return the minimum unsigned long value after comparing the argument value to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MOD` (ip_address_at i)

Return the Unsigned Long Value that is the renaminder after dividing the current unsigned long value by the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MOD` (unsigned_long_at i)

Return the Unsigned Long Value that is the renaminder after dividing the current unsigned long value by the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MOD` (num_at i)

Return the Number Value that is the renaminder after dividing the current number value by the argument.

`Parameters``:`

i- Number

`Returns:` num_at

`*MOD` (time_local_at i)

Return the Unsigned Long Value that is the renaminder after dividing the current unsigned long value by the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MOD` (time_at i)

Return the Unsigned Long Value that is the renaminder after dividing the current unsigned long value by the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MUL` (double_at i)

Return the Double Value after multiplying the argument to the current double value.

`Parameters``:`

i- Double

`Returns:` double_at

`*MUL` (ip_address_at i)

Return the Unsigned Long Value after multiplying the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MUL` (unsigned_long_at i)

Return the Unsigned Long Value after multiplying the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MUL` (num_at i)

Return the Number Value after multiplying the argument to the current number value.

`Parameters``:`

i- Number

`Returns:` num_at

`*MUL` (time_local_at i)

Return the Unsigned Long Value after multiplying the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MUL` (time_at i)

Return the Unsigned Long Value after multiplying the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*NEG`

Return the Number Value after negating the current number value.

`Returns:` num_at

`*NE` (dns_type_e m)

The result is Boolean FALSE if the input argument is equal to the DNS record type represented by this object.

`Parameters` (expressions not allowed) `:`

m- Dns record type

`Returns:` bool_at

`*NE` (double_at i)

Returns Boolean TRUE if the double value is not equal to the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`*NE` (ip_address_at i)

Returns Boolean TRUE if the unsigned long value is not equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*NE` (unsigned_long_at i)

Returns Boolean TRUE if the unsigned long value is not equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*NE` (num_at i)

Returns Boolean TRUE if the number value is not equal to the argument.

`Parameters``:`

i- Number

`Returns:` bool_at

`*NE` (time_local_at i)

Returns Boolean TRUE if the unsigned long value is not equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*NE` (time_at i)

Returns Boolean TRUE if the unsigned long value is not equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*RSHIFT` (`uint` i)

Return the Number Value after bitwise right shifting the current number value by the argument number of bits. Note that the number of bits shifted is i modulo 32. For example, let HTTP.REQ.URL.LENGTH be 4. Then, HTTP.REQ.URL.LENGTH.RSHIFT(1) = HTTP.REQ.URL.LENGTH.RSHIFT(33) = 2, since 33 on division by 32 yields a remainder of 1.

`Parameters``:`

i- Right Shift Length

`Returns:` num_at

`*SIGNED16_STRING` (endian_e endianness)

Create a signed 16-bit binary string from the number.

`Parameters` (expressions not allowed) `:`

endianness- Select little or big endian

`Returns:` text_t

`*SIGNED32_STRING` (endian_e endianness)

Create a signed 32-bit binary string from the number.

`Parameters` (expressions not allowed) `:`

endianness- Select little or big endian

`Returns:` text_t

`*SIGNED8_STRING`

Create a signed 8-bit binary string from the number.

`Returns:` text_t

`*SUB` (double_at i)

Return the Double Value after subtracting the argument from the current double value.

`Parameters``:`

i- Double

`Returns:` double_at

`*SUB` (ip_address_at i)

Return the Unsigned Long Value after subtracting the argument from the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*SUB` (unsigned_long_at i)

Return the Unsigned Long Value after subtracting the argument from the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*SUB` (num_at i)

Return the Number Value after subtracting the argument from the current number value.

`Parameters``:`

i- Number

`Returns:` num_at

`*SUB` (time_local_at i)

Return the Unsigned Long Value after subtracting the argument from the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*SUB` (time_at i)

Return the Unsigned Long Value after subtracting the argument from the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*TYPECAST_DOUBLE_AT`

Typecast the Number Value to a Double value.

`Returns:` double_at

`*TYPECAST_IP_ADDRESS_AT`

Typecast the Number Value to an IP Address value.

`Returns:` ip_address_at

`*TYPECAST_TEXT_T`

Typecast the Number Value to its string representation.

`Returns:` text_t

`*TYPECAST_TIME_AT`

Typecast the Number Value to a Time value.

`Returns:` time_at

`*TYPECAST_TIME_LOCAL_AT`

Typecast the Number Value to a local time value.

`Returns:` time_local_at

`*TYPECAST_UNSIGNED_LONG_AT`

Typecast the Number Value to a Unsigned Long value.

`Returns:` unsigned_long_at

`*UNSIGNED16_STRING` (endian_e endianness)

Create an unsigned 16-bit binary string from the number.

`Parameters` (expressions not allowed) `:`

endianness- Select little or big endian

`Returns:` text_t

`*UNSIGNED32_STRING` (endian_e endianness)

Create an unsigned 32-bit binary string from the number.

`Parameters` (expressions not allowed) `:`

endianness- Select little or big endian

`Returns:` text_t

`*UNSIGNED64_STRING` (endian_e endianness)

Create an unsigned 64-bit binary string from the number.

`Parameters` (expressions not allowed) `:`

endianness- Select little or big endian

`Returns:` text_t

`*UNSIGNED8_STRING`

Create an unsigned 8-bit binary string from the number.

`Returns:` text_t

`*WEEKDAY_STRING`

Given the numeric day of the week, e.g. SYS.TIME.WEEKDAY, return the long form of the string name for that day, e.g. 0 = "Sunday", 6 = "Saturday".

`Returns:` text_t

`*WEEKDAY_STRING_SHORT`

Given the numeric day of the week, e.g. SYS.TIME.WEEKDAY, return the short form of the string name for that day, e.g. 0 = "Sun", 6 = "Sat".

`Returns:` text_t

DOUBLE_AT

Double Value

This topic lists the expressions that are provided by this class.

- `ABS`

  Return absolute double value of the double value.

`Returns:` double_at

`ADD` (double_at i)

Return the Double Value after adding the argument to the current double value.

`Parameters``:`

i- Double

`Returns:` double_at

`ADD` (ip_address_at i)

Return the Double Value after adding the argument to the current double value.

`Parameters``:`

i- Double

`Returns:` double_at

`ADD` (num_at i)

Return the Double Value after adding the argument to the current double value.

`Parameters``:`

i- Double

`Returns:` double_at

`ADD` (time_local_at i)

Return the Double Value after adding the argument to the current double value.

`Parameters``:`

i- Double

`Returns:` double_at

`ADD` (time_at i)

Return the Double Value after adding the argument to the current double value.

`Parameters``:`

i- Double

`Returns:` double_at

`ADD` (unsigned_long_at i)

Return the Double Value after adding the argument to the current double value.

`Parameters``:`

i- Double

`Returns:` double_at

`APPEND` (text_t str)

Appends the given string to the string representation of the current double.

`Parameters``:`

str- the string to append.

`Returns:` text_t

`BETWEEN` (double_at i, double_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`BETWEEN` (double_at i, ip_address_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`BETWEEN` (double_at i, num_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`BETWEEN` (double_at i, time_local_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`BETWEEN` (double_at i, time_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`BETWEEN` (double_at i, unsigned_long_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`BETWEEN` (ip_address_at i, double_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`BETWEEN` (ip_address_at i, ip_address_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`BETWEEN` (ip_address_at i, num_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`BETWEEN` (ip_address_at i, time_local_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`BETWEEN` (ip_address_at i, time_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`BETWEEN` (ip_address_at i, unsigned_long_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`BETWEEN` (num_at i, double_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`BETWEEN` (num_at i, ip_address_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`BETWEEN` (num_at i, num_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`BETWEEN` (num_at i, time_local_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`BETWEEN` (num_at i, time_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`BETWEEN` (num_at i, unsigned_long_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`BETWEEN` (time_local_at i, double_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`BETWEEN` (time_local_at i, ip_address_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`BETWEEN` (time_local_at i, num_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`BETWEEN` (time_local_at i, time_local_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`BETWEEN` (time_local_at i, time_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`BETWEEN` (time_local_at i, unsigned_long_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`BETWEEN` (time_at i, double_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`BETWEEN` (time_at i, ip_address_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`BETWEEN` (time_at i, num_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`BETWEEN` (time_at i, time_local_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`BETWEEN` (time_at i, time_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`BETWEEN` (time_at i, unsigned_long_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`BETWEEN` (unsigned_long_at i, double_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`BETWEEN` (unsigned_long_at i, ip_address_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`BETWEEN` (unsigned_long_at i, num_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`BETWEEN` (unsigned_long_at i, time_local_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`BETWEEN` (unsigned_long_at i, time_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`BETWEEN` (unsigned_long_at i, unsigned_long_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`DIV` (double_at i)

Return the Double Value after dividing the current double value by the argument.

`Parameters``:`

i- Double

`Returns:` double_at

`DIV` (ip_address_at i)

Return the Double Value after dividing the current double value by the argument.

`Parameters``:`

i- Double

`Returns:` double_at

`DIV` (num_at i)

Return the Double Value after dividing the current double value by the argument.

`Parameters``:`

i- Double

`Returns:` double_at

`DIV` (time_local_at i)

Return the Double Value after dividing the current double value by the argument.

`Parameters``:`

i- Double

`Returns:` double_at

`DIV` (time_at i)

Return the Double Value after dividing the current double value by the argument.

`Parameters``:`

i- Double

`Returns:` double_at

`DIV` (unsigned_long_at i)

Return the Double Value after dividing the current double value by the argument.

`Parameters``:`

i- Double

`Returns:` double_at

`EQ` (double_at i)

Returns Boolean TRUE if the double value is equal to the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`EQ` (ip_address_at i)

Returns Boolean TRUE if the double value is equal to the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`EQ` (num_at i)

Returns Boolean TRUE if the double value is equal to the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`EQ` (time_local_at i)

Returns Boolean TRUE if the double value is equal to the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`EQ` (time_at i)

Returns Boolean TRUE if the double value is equal to the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`EQ` (unsigned_long_at i)

Returns Boolean TRUE if the double value is equal to the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`GE` (double_at i)

Returns Boolean TRUE if the double value is greater than or equal to the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`GE` (ip_address_at i)

Returns Boolean TRUE if the double value is greater than or equal to the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`GE` (num_at i)

Returns Boolean TRUE if the double value is greater than or equal to the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`GE` (time_local_at i)

Returns Boolean TRUE if the double value is greater than or equal to the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`GE` (time_at i)

Returns Boolean TRUE if the double value is greater than or equal to the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`GE` (unsigned_long_at i)

Returns Boolean TRUE if the double value is greater than or equal to the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`GT` (double_at i)

Returns Boolean TRUE if the double value is greater than the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`GT` (ip_address_at i)

Returns Boolean TRUE if the double value is greater than the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`GT` (num_at i)

Returns Boolean TRUE if the double value is greater than the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`GT` (time_local_at i)

Returns Boolean TRUE if the double value is greater than the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`GT` (time_at i)

Returns Boolean TRUE if the double value is greater than the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`GT` (unsigned_long_at i)

Returns Boolean TRUE if the double value is greater than the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`LE` (double_at i)

Returns Boolean TRUE if the double value is lesser than or equal to the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`LE` (ip_address_at i)

Returns Boolean TRUE if the double value is lesser than or equal to the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`LE` (num_at i)

Returns Boolean TRUE if the double value is lesser than or equal to the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`LE` (time_local_at i)

Returns Boolean TRUE if the double value is lesser than or equal to the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`LE` (time_at i)

Returns Boolean TRUE if the double value is lesser than or equal to the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`LE` (unsigned_long_at i)

Returns Boolean TRUE if the double value is lesser than or equal to the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`LT` (double_at i)

Returns Boolean TRUE if the double value is lesser than the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`LT` (ip_address_at i)

Returns Boolean TRUE if the double value is lesser than the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`LT` (num_at i)

Returns Boolean TRUE if the double value is lesser than the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`LT` (time_local_at i)

Returns Boolean TRUE if the double value is lesser than the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`LT` (time_at i)

Returns Boolean TRUE if the double value is lesser than the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`LT` (unsigned_long_at i)

Returns Boolean TRUE if the double value is lesser than the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`MAX` (double_at i)

Return the maximum double value after comparing the argument with the current double value.

`Parameters``:`

i- Double

`Returns:` double_at

`MAX` (ip_address_at i)

Return the maximum double value after comparing the argument with the current double value.

`Parameters``:`

i- Double

`Returns:` double_at

`MAX` (num_at i)

Return the maximum double value after comparing the argument with the current double value.

`Parameters``:`

i- Double

`Returns:` double_at

`MAX` (time_local_at i)

Return the maximum double value after comparing the argument with the current double value.

`Parameters``:`

i- Double

`Returns:` double_at

`MAX` (time_at i)

Return the maximum double value after comparing the argument with the current double value.

`Parameters``:`

i- Double

`Returns:` double_at

`MAX` (unsigned_long_at i)

Return the maximum double value after comparing the argument with the current double value.

`Parameters``:`

i- Double

`Returns:` double_at

`MIN` (double_at i)

Return the minimum double value after comparing the argument with the current double value.

`Parameters``:`

i- Double

`Returns:` double_at

`MIN` (ip_address_at i)

Return the minimum double value after comparing the argument with the current double value.

`Parameters``:`

i- Double

`Returns:` double_at

`MIN` (num_at i)

Return the minimum double value after comparing the argument with the current double value.

`Parameters``:`

i- Double

`Returns:` double_at

`MIN` (time_local_at i)

Return the minimum double value after comparing the argument with the current double value.

`Parameters``:`

i- Double

`Returns:` double_at

`MIN` (time_at i)

Return the minimum double value after comparing the argument with the current double value.

`Parameters``:`

i- Double

`Returns:` double_at

`MIN` (unsigned_long_at i)

Return the minimum double value after comparing the argument with the current double value.

`Parameters``:`

i- Double

`Returns:` double_at

`MUL` (double_at i)

Return the Double Value after multiplying the argument to the current double value.

`Parameters``:`

i- Double

`Returns:` double_at

`MUL` (ip_address_at i)

Return the Double Value after multiplying the argument to the current double value.

`Parameters``:`

i- Double

`Returns:` double_at

`MUL` (num_at i)

Return the Double Value after multiplying the argument to the current double value.

`Parameters``:`

i- Double

`Returns:` double_at

`MUL` (time_local_at i)

Return the Double Value after multiplying the argument to the current double value.

`Parameters``:`

i- Double

`Returns:` double_at

`MUL` (time_at i)

Return the Double Value after multiplying the argument to the current double value.

`Parameters``:`

i- Double

`Returns:` double_at

`MUL` (unsigned_long_at i)

Return the Double Value after multiplying the argument to the current double value.

`Parameters``:`

i- Double

`Returns:` double_at

- `NEG`

  Return the Double Value after negating the current double value.

`Returns:` double_at

`NE` (double_at i)

Returns Boolean TRUE if the double value is not equal to the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`NE` (ip_address_at i)

Returns Boolean TRUE if the double value is not equal to the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`NE` (num_at i)

Returns Boolean TRUE if the double value is not equal to the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`NE` (time_local_at i)

Returns Boolean TRUE if the double value is not equal to the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`NE` (time_at i)

Returns Boolean TRUE if the double value is not equal to the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`NE` (unsigned_long_at i)

Returns Boolean TRUE if the double value is not equal to the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`SUB` (double_at i)

Return the Double Value after subtracting the argument from the current double value.

`Parameters``:`

i- Double

`Returns:` double_at

`SUB` (ip_address_at i)

Return the Double Value after subtracting the argument from the current double value.

`Parameters``:`

i- Double

`Returns:` double_at

`SUB` (num_at i)

Return the Double Value after subtracting the argument from the current double value.

`Parameters``:`

i- Double

`Returns:` double_at

`SUB` (time_local_at i)

Return the Double Value after subtracting the argument from the current double value.

`Parameters``:`

i- Double

`Returns:` double_at

`SUB` (time_at i)

Return the Double Value after subtracting the argument from the current double value.

`Parameters``:`

i- Double

`Returns:` double_at

`SUB` (unsigned_long_at i)

Return the Double Value after subtracting the argument from the current double value.

`Parameters``:`

i- Double

`Returns:` double_at

- `TYPECAST_NUM_AT`

Typecast the Double Value to a Number value.

`Returns:` num_at

- `TYPECAST_TEXT_T`

  Typecast the Double Value to its string representation.

`Returns:` text_t

- `TYPECAST_UNSIGNED_LONG_AT`

  Typecast the Double Value to a Unsigned Long value.

`Returns:` unsigned_long_at

DOUBLE_FORMAT_E

Double Format Enum

Enumerations

DECIMAL

Decimal representation of a positive or a negative double precisions floating point value. White spaces before and after the number are OK

DECIMAL_PREFIX

Decimal representation of a positive or a negative double precisions floating point value followed by arbitrary characters. Examples " -123.45" " 234e5 " "- 123e5abc" "234e5 abc"

DOUBLE_T

Provides operations to treat the underlying text as a Double

This topic lists the expressions that are provided by this class.

`*Note` *: Expressions with the * symbol are inherited / promoted from text_t double_at

- `TYPECAST_DOUBLE_AT`

  Convert double_t to double_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_at : Double Value)

`Returns:` double_at

`*TYPECAST_TEXT_T`

Convert double_t to text_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (text_t : Designates any piece of text.)

`Returns:` text_t

`*ABS`

Return absolute double value of the double value.

`Returns:` double_at

`*ADD` (double_at i)

Return the Double Value after adding the argument to the current double value.

`Parameters``:`

i- Double

`Returns:` double_at

`*ADD` (ip_address_at i)

Return the Double Value after adding the argument to the current double value.

`Parameters``:`

i- Double

`Returns:` double_at

`*ADD` (num_at i)

Return the Double Value after adding the argument to the current double value.

`Parameters``:`

i- Double

`Returns:` double_at

`*ADD` (time_local_at i)

Return the Double Value after adding the argument to the current double value.

`Parameters``:`

i- Double

`Returns:` double_at

`*ADD` (time_at i)

Return the Double Value after adding the argument to the current double value.

`Parameters``:`

i- Double

`Returns:` double_at

`*ADD` (unsigned_long_at i)

Return the Double Value after adding the argument to the current double value.

`Parameters``:`

i- Double

`Returns:` double_at

`*AFTER_REGEX` (`re` regex)

Selects the text after the portion that matches the given regular expression argument. The first match is returned when multiple matches occur in the text. The match may occur anywhere within the text - if you wish to "anchor" this, use "\^" at the start of the regex and/or "$" at the end of the regex. When the regular expression does not match the given string, a Text object of length of 0 is returned.

Example: HTTP.REQ.HEADER("etag").AFTER_REGEX(re/KX/) will select "DAPPER" from "KXDAPPER". This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

regex- Regular Expression

`Returns:` text_t

`*AFTER_STR_ANY` (text_t patset_name)

Selects the Text that is present after the first occurrence of any of the strings that are bound to the patset named by the string argument. If there is no match to any of the strings bound to the patset in the current Text object then the result Text object has 0 length. The patset cannot have strings longer than 255 characters. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` text_t

`*AFTER_STR` (text_t s)

Selects the Text that is present after the first occurrence of the string argument. If there is no match for the argument in the current Text then the result Text object has 0 length. The input string cannot be bigger than 255 characters. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*APPEND` (bool_at b)

Appends the given boolean's string representation to the current string.

`Parameters``:`

b- the boolean value to append.

`Returns:` text_t

`*APPEND` (double_at i)

Appends the given double's string representation to the current string.

`Parameters``:`

i- the double value to append.

`Returns:` text_t

`*APPEND` (ip_address_at addr)

Appends the given IPv4's string representation to the current string.

`Parameters``:`

addr- the IPv4 address to append.

`Returns:` text_t

`*APPEND` (num_at i)

Appends the given number's string representation to the current string.

`Parameters``:`

i- the number value to append.

`Returns:` text_t

`*APPEND` (time_local_at t)

Appends the given time's string representation to the current string.

`Parameters``:`

t- the time value to append.

`Returns:` text_t

`*APPEND` (time_at t)

Appends the given time's string representation to the current string.

`Parameters``:`

t- the time value to append.

`Returns:` text_t

`*APPEND` (unsigned_long_at i)

Appends the given unsigned long's string representation to the current string.

`Parameters``:`

i- the unsigned long value to append.

`Returns:` text_t

`*APPEND` (ipv6_address_at addr)

Appends the given IPv6's string representation to the current string.

`Parameters``:`

addr- the IPv6 address to append.

`Returns:` text_t

`*APPEND` (ipv6_subnet_at addr)

Appends the given IPv6 subnet's string representation to the current string.

`Parameters``:`

addr- the IPv6 subnet to append.

`Returns:` text_t

`*APPEND` (mac_address_at addr)

Appends the given MAC's string representation to the current string.

`Parameters``:`

addr- the MAC address to append.

`Returns:` text_t

`*APPEND` (text_t str)

Appends the given string to the string representation of the current double.

`Parameters``:`

str- the string to append.

`Returns:` text_t

`*APPEND` (time_at t)

Appends the given time's string representation to the current string.

`Parameters``:`

t- the time value to append.

`Returns:` text_t

`*B64DECODE`

Decodes the selected text using base64 decoding.

For example, the string "TWFu" is converted to "Man"

`Returns:` text_t

`*B64ENCODE`

Encodes the selected text using base64 encoding.

For example, the string "Man" is converted to "TWFu"

`Returns:` text_t

`*BEFORE_REGEX` (`re` regex)

Selects the text before the portion that matches the given regular expression argument. The first match is returned when multiple matches occur in the text. The match may occur anywhere within the text - if you wish to "anchor" this, use "\^" at the start of the regex and/or "$" at the end of the regex. When the regular expression does not match the given string, a Text object of length of 0 is returned.

For example: HTTP.RES.HEADER("content-type").BEFORE_REGEX(re#/#) will select "text" from "text/plain". This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

regex- Regular Expression

`Returns:` text_t

`*BEFORE_STR_ANY` (text_t patset_name)

Selects the Text that is present before the first occurrence of any of the strings that are bound to the patset or datasetnamed by the string argument. If there is no match to any of the strings bound to the patset in the current Text object then the result Text object has 0 length. The patset cannot have strings longer than 255 characters. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` text_t

`*BEFORE_STR` (text_t s)

Selects the Text that is present before the first occurrence of the string argument. If there is no match for the argument in the current Text object then the result Text object has 0 length. The input string cannot be bigger than 255 characters. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*BETWEEN` (double_at i, double_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (double_at i, ip_address_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (double_at i, num_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (double_at i, time_local_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (double_at i, time_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (double_at i, unsigned_long_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (ip_address_at i, double_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (ip_address_at i, ip_address_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (ip_address_at i, num_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (ip_address_at i, time_local_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (ip_address_at i, time_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (ip_address_at i, unsigned_long_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (num_at i, double_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (num_at i, ip_address_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (num_at i, num_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (num_at i, time_local_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (num_at i, time_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (num_at i, unsigned_long_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (time_local_at i, double_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (time_local_at i, ip_address_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (time_local_at i, num_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (time_local_at i, time_local_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (time_local_at i, time_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (time_local_at i, unsigned_long_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (time_at i, double_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (time_at i, ip_address_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (time_at i, num_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (time_at i, time_local_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (time_at i, time_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (time_at i, unsigned_long_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (unsigned_long_at i, double_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (unsigned_long_at i, ip_address_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (unsigned_long_at i, num_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (unsigned_long_at i, time_local_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (unsigned_long_at i, time_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (unsigned_long_at i, unsigned_long_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (text_t start, text_t end)

Results in Boolean TRUE value if length of the Text object is greater than or equal to the sum of the Start and End argument lengths and if the prefix of the Text object matches the Start string argument and if the Suffix of the Text object matches the End string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

start- Start

end- End

`Returns:` bool_at

`*BIN_DECODE` (binary_encoding_e encoding)

Decode the encoded input into its original byte sequence. An incorrectly enooded input will result in an Undef error.

`Parameters` (expressions not allowed) `:`

encoding- specifies how the bytes are encoded.

`Returns:` text_t

`*BIN_ENCODE` (binary_encoding_e encoding)

Encode the input byte sequence. Note that BIN_ENCODE(hex_colons) is equivalent to BLOB_TO_HEX().

`Parameters` (expressions not allowed) `:`

encoding- specifies how the bytes are to be encoded.

`Returns:` text_t

`*BLOB_TO_HEX`

Convert to hexadecimal representation and select text.

For example, the byte string abc is converted to 61:62:63.

`Returns:` text_t

`*COMPARE` (text_t s)

Results in a Number Value which is the result of comparison of the input argument with the Text object. The result is greater than 0 if the Text object is lexicographically greater than the argument. The result is 0 if the Text object and the argument match. The result is less than 0 if the Text object is lexicographically lesser than the argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` num_at

`*CONTAINS_ANY` (text_t patset_name)

Results in Boolean TRUE value if the Text contains any of the strings that are bound to the patset or dataset named by the string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed)`:`

patset_name- Pattern Set Name

`Returns:` bool_at

`*CONTAINS_INDEX` (text_t patset_name)

Returns the numerical index of the matching string, if the Text contains any of the strings that are bound to the patset or dataset named by the string argument. Returns 0 if there is no match. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed)`:`

patset_name- Pattern Set Name

`Returns:` num_at

`*CONTAINS` (text_t s)

Results in Boolean TRUE value if the Text contains the string given in the argument. The input string cannot be bigger than 255 characters. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*CRC32`

Returns a 32-bit integer computed by applying a CRC (cyclic redundancy check) function to the selected text. This is the CRC function used by Ethernet, MPEG-2, PKZIP, GZIP, PNG, and many other applications. For example, the expression to compute the CRC value of the (first 1000 bytes of the) body of an HTTP request is: HTTP.REQ.BODY(1000).CRC32

`Returns:` num_at

`*DECODE_USING_TEXT_MODE`

Decodes the selected text using the currently configured text encoding methods like URLENCODED, BACKSLASH_ENCODED, PLUS_AS_SPACE, NOURLENCODED, NO_BACKSLASH_ENCODED and NO_PLUS_AS_SPACE. Text encoding methods are set using SET_TEXT_MODE method.

`Returns:` text_t

`*DECRYPT`

Decrypt the selected base64-encoded ciphertext using the configured encryptionParams.

`Returns:` text_t

`*DECRYPT` (binary_encoding_e in_encoding)

Decrypt the selected ciphertext using the configured encryptionParams.

`Parameters` (expressions not allowed) `:`

in_encoding- specifies how the input ciphertext is encoded. If the ciphertext is not encoded as specified, causes an Undef error.

`Returns:` text_t

`*DECRYPT` (text_t encryptionKey)

Decrypt the selected base64-encoded encrypted bytes using the configured encryption key.

`Parameters` (expressions not allowed) `:`

encryptionKey- identifies the encryptionKey object to provide the cipher method, mode, padding, key, encrypted format and optional initialization vector (IV).

`Returns:` text_t

`*DECRYPT` (text_t encryptionKey, binary_encoding_e in_encoding)

Decrypt the selected base64-encoded encrypted bytes using the configured encryption key.

`Parameters` (expressions not allowed) `:`

encryptionKey- identifies the encryptionKey object to provide the cipher method, mode, padding, key, encrypted format, and optional initialization vector (IV).

in_encoding- specifies how the input ciphertext is encoded. If the ciphertext is not encoded as specified, causes an Undef error.

`Returns:` text_t

`*DIGEST` (digest_method_e method)

Returns a byte sequence computed by applying the the specified message digest method to the selected text.

`Parameters` (expressions not allowed) `:`

method- digest method to apply to the input text

`Returns:` text_t

`*DIV` (double_at i)

Return the Double Value after dividing the current double value by the argument.

`Parameters``:`

i- Double

`Returns:` double_at

`*DIV` (ip_address_at i)

Return the Double Value after dividing the current double value by the argument.

`Parameters``:`

i- Double

`Returns:` double_at

`*DIV` (num_at i)

Return the Double Value after dividing the current double value by the argument.

`Parameters``:`

i- Double

`Returns:` double_at

`*DIV` (time_local_at i)

Return the Double Value after dividing the current double value by the argument.

`Parameters``:`

i- Double

`Returns:` double_at

`*DIV` (time_at i)

Return the Double Value after dividing the current double value by the argument.

`Parameters``:`

i- Double

`Returns:` double_at

`*DIV` (unsigned_long_at i)

Return the Double Value after dividing the current double value by the argument.

`Parameters``:`

i- Double

`Returns:` double_at

`*ENCRYPT`

Encrypt the selected plaintext bytes using the configured encryptionParams. The resulting ciphertext is base64-encoded.

`Returns:` text_t

`*ENCRYPT` (binary_encoding_e out_encoding)

Encrypt the selected plaintext bytes using the configured encryptionParams.

`Parameters` (expressions not allowed) `:`

out_encoding- specifies how the resulting ciphertext is encoded.

`Returns:` text_t

`*ENCRYPT` (text_t encryptionKey)

Encrypt the selected cleartext bytes using the configured encryption key.

`Parameters` (expressions not allowed) `:`

encryptionKey- identifies the encryptionKey object to provide the cipher method, mode, padding, key, encrypted format and optional initialization vector (IV).

`Returns:` text_t

`*ENCRYPT` (text_t encryptionKey, binary_encoding_e out_encoding)

Encrypt the selected cleartext bytes using the configured encryption key.

`Parameters` (expressions not allowed) `:`

encryptionKey- identifies the encryptionKey object to provide the cipher method, mode, padding, key, encrypted format and optional initialization vector (IV).

out_encoding- specifies how the resulting ciphertext is encoded.

`Returns:` text_t

`*ENDSWITH_ANY` (text_t patset_name)

Results in Boolean TRUE value if the Text ends with any of the strings that are bound to the patset or dataset named by the string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` bool_at

`*ENDSWITH_INDEX` (text_t patset_name)

Returns the numerical index of the matching string, if the Text ends with any of the strings that are bound to the patset or dataset named by the string argument. Returns 0 if there is no match. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` num_at

`*ENDSWITH` (text_t end)

Results in Boolean TRUE value if a suffix of the Text object matches the string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

end- String

`Returns:` bool_at

`*EQUALS_ANY` (text_t patset_name)

Results in Boolean TRUE value if the Text equals any of the strings that are bound to the patset or dataset named by the string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` bool_at

`*EQUALS_INDEX` (text_t patset_name)

Returns the numerical index of the matching string, if the Text equals any of the strings that are bound to the patset or dataset named by the string argument. Returns 0 if there is no match. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` num_at

`*EQ` (double_at i)

Returns Boolean TRUE if the double value is equal to the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`*EQ` (ip_address_at i)

Returns Boolean TRUE if the double value is equal to the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`*EQ` (num_at i)

Returns Boolean TRUE if the double value is equal to the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`*EQ` (time_local_at i)

Returns Boolean TRUE if the double value is equal to the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`*EQ` (time_at i)

Returns Boolean TRUE if the double value is equal to the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`*EQ` (unsigned_long_at i)

Returns Boolean TRUE if the double value is equal to the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`*EQ` (text_t s)

Results in Boolean TRUE value if the Text object matches the input argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*GET_SIGNED16` (`uint` n, endian_e endianness)

Get the 16-bit signed binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

endianness- Select little or big endian

`Returns:` num_at

`*GET_SIGNED32` (`uint` n, endian_e endianness)

Get the 32-bit signed binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

endianness- Select little or big endian

`Returns:` num_at

`*GET_SIGNED8` (`uint` n)

Get the 8-bit signed binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

`Returns:` num_at

`*GET_UNSIGNED16` (`uint` n, endian_e endianness)

Get the 16-bit unsigned binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

endianness- Select little or big endian

`Returns:` num_at

`*GET_UNSIGNED32` (`uint` n, endian_e endianness)

Get the 32-bit unsigned binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

endianness- Select little or big endian

`Returns:` unsigned_long_at

`*GET_UNSIGNED64` (`uint` n, endian_e endianness)

Get the 64-bit unsigned binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

endianness- Select little or big endian

`Returns:` unsigned_long_at

`*GET_UNSIGNED8` (`uint` n)

Get the 8-bit unsigned binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

`Returns:` num_at

`*GET_URLSET_METADATA` (text_t urlset_name)

Returns metadata value corresponding to pattern in the urlset. The matching is case-insensitive for domains, but case-sensitive for paths. If no pattern is matched within the urlset, the return value is a NULL string. For example:

- HTTP.REQ.HOST.APPEND(HTTP.REQ.URL).GET_URLSET_METADATA("urlset_forbidden") returns value when the combined domain and URL is looked up in the urlset whose name is "urlset_forbidden".

`Parameters` (expressions not allowed) `:`

urlset_name- urlset name

`Returns:` text_t

`*GE` (double_at i)

Returns Boolean TRUE if the double value is greater than or equal to the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`*GE` (ip_address_at i)

Returns Boolean TRUE if the double value is greater than or equal to the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`*GE` (num_at i)

Returns Boolean TRUE if the double value is greater than or equal to the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`*GE` (time_local_at i)

Returns Boolean TRUE if the double value is greater than or equal to the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`*GE` (time_at i)

Returns Boolean TRUE if the double value is greater than or equal to the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`*GE` (unsigned_long_at i)

Returns Boolean TRUE if the double value is greater than or equal to the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`*GE` (text_t s)

Results in Boolean TRUE value if the Text object is greater than or equal to the input argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*GRPC`

Interprets a text_t string as a Protocol Buffer (protocol_buffer_t type). Example: HTTP.REQ.BODY(1000).GRPC.STRING(1).EQ("bookname")

`Returns:` protocol_buffer_t

`*GT` (double_at i)

Returns Boolean TRUE if the double value is greater than the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`*GT` (ip_address_at i)

Returns Boolean TRUE if the double value is greater than the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`*GT` (num_at i)

Returns Boolean TRUE if the double value is greater than the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`*GT` (time_local_at i)

Returns Boolean TRUE if the double value is greater than the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`*GT` (time_at i)

Returns Boolean TRUE if the double value is greater than the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`*GT` (unsigned_long_at i)

Returns Boolean TRUE if the double value is greater than the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`*GT` (text_t s)

Results in Boolean TRUE value if the Text object is greater than the input argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*HASH`

Returns a positive 31 bit integer value computed by applying a proprietary NetScaler hash function to the selected text. This function is not case- sensitive and ignores whitespaces. For example, applying the HASH function to two strings "Ab c" and "abc" would produce the same value. This function should not be used for security purposes; use instead the DIGEST function with one of the standard digest methods.

`Returns:` num_at

`*HMAC` (text_t hmacKey)

Returns a byte sequence computed by applying the HMAC (Hash Message Authenticastion Code) function to the selected text using the configured HMAC key.

`Parameters` (expressions not allowed) `:`

hmacKey- indentifies the hmacKey object to provide the digest (hash) method and the key.

`Returns:` text_t

`*HMAC` (text_t hmacKey, binary_encoding_e out_encoding)

Returns a byte sequence computed by applying the HMAC (Hash Message Authenticastion Code) function to the selected text using the configured HMAC key .

`Parameters` (expressions not allowed) `:`

hmacKey- indentifies the hmacKey object to provide the digest (hash) method and the key.

out_encoding- specifies how the resulting HMAC is encoded.

`Returns:` text_t

`*HTML_XML_SAFE`

Apply XML safe transform and select text.

Converts '<', '>' and '&' in the input text to '<', '>' and '&' respectively; other characters in the input are not modified. This transform safeguards against XSS based attacks. This is a read only operation.

`Returns:` text_t

`*HTTP_HEADER_SAFE`

Apply Header safe transform and select text. Converts all new line ('\\n') characters present in the input text to '%0A' so that they can safely be used in HTTP headers. This transform safeguards against response-splitting attacks. This is a read only operation.

`Returns:` text_t

`*HTTP_URL_SAFE`

Apply URL safe transform and select text. Converts URL unsafe characters to corresponding '%xx' values and retains the rest. This is a read only operation.

```
Based on RFC2396, following are considered URL safe characters:

    Alpha-numeric characters: a-z, A-Z, 0-9

    Hyphen and underscore: "-", "_"

    Dot: "."

    Exclamation mark: "!"

    Tilde: "~"

    Asterix: "&ast;"

    Single quote: "'"

    Open and close parentheses: "(", ")"

    Semi-colon: ";"

    Colon: ":"

    At symbol: "@"

    Question mark: "?"

    Equals: "="

    Dollar: "$"

    Percent: "%"
```

```
    Ampersand: "&"

    Plus: "+"

    Comma: ","

    Forward slash: ".html"
```

The rest are converted to %XX encoding, 'XX' is the hex-based representation of the input character. If the requirement is to encode all but URL unreserved characters, please consider using URL_RESERVED_CHARS_SAFE method.

`Returns:` text_t

`*IS_BOOL_AT`

Results in Boolean TRUE value if the Text is of boolean type.

`Returns:` bool_at

`*IS_DOUBLE_AT`

Results in Boolean TRUE value if the Text is of double data type.

`Returns:` bool_at

`*IS_IPV6_AT`

Results in Boolean TRUE value if the Text is of IPv6 data type.

`Returns:` bool_at

`*IS_IPV6_SUBNET_AT`

Results in Boolean TRUE value if the Text is of IPv6 subnet data type.

`Returns:` bool_at

`*IS_IP_AT`

Results in Boolean TRUE value if the Text is of IPv4 data type.

`Returns:` bool_at

`*IS_MAC_ADDRESS_AT`

Results in Boolean TRUE value if the Text is of mac address data type.

`Returns:` bool_at

`*IS_NUM_AT`

Results in Boolean TRUE value if the Text is of number type.

`Returns:` bool_at

`*IS_NUM_AT` (num_format_e format)

Results in Boolean TRUE value if the Text is of number type with given input base.

`Parameters` (expressions not allowed) `:`

format- number format

`Returns:` bool_at

`*IS_STRINGMAP_KEY` (text_t string_map_name)

Returns true if the string that it operates on is present in the string map. Text mode IGNORECASE, NOIGNORECASE - controls whether key lookup in string map is case sensitive or not. For example:

- HTTP.REQ.URL.IS_STRINGMAP_KEY("url_stringmap") returns true if value of HTTP.REQ.URL is present as key in the string map whose name is "url_stringmap".
- HTTP.REQ.URL.SET_TEXT_MODE(IGNORECASE). IS_STRINGMAP_KEY("url_stringmap") returns true if value of HTTP.REQ.URL is present as key in the string map whose name is "url_stringmap". Key lookup in this case is done case-insensitively.

`Parameters` (expressions not allowed) `:`

string_map_name- identifies the string map.

`Returns:` bool_at

`*IS_TIME_AT`

Results in Boolean TRUE if the Text follows any of the standard time formats given below, otherwise false. Tue, 05 Nov 1994 08:12:31 GMT RFC822 Tuesday, 05-Nov-94 08:12:31 GMT RFC850 Tue Nov 4 08:12:31 1994 asctime

`Returns:` bool_at

`*IS_UNSIGNED_LONG_AT`

Results in Boolean TRUE value if the Text is of unsigned long data type.

`Returns:` bool_at

`*IS_UNSIGNED_LONG_AT` (num_format_e format)

Results in Boolean TRUE value if the Text is of unsigned long data type with given input base.

`Parameters` (expressions not allowed) `:`

format- number format

`Returns:` bool_at

`*JWT_VERIFY_CERTKEY` (text_t certkey_name)

Verifies the signature on the input JSON Web Token (JWT), using the RSA public key in the X.509 certificate in the specified certkey object. The token has the format HEADER.PAYLOAD.SIGNATURE where

- HEADER is a base64-encoded JSON structure indicating a signature algorithm and token type, e.g.'{"alg":"RS256","typ":"JWT"}'
- PAYLOAD is a base64-encoded JSON structure with asserted claims, e.g. '{"loggedInAs":"admin","iat":1422779638}'
- SIGNATURE is the base64-encoded bytes for the signature on HEADER.PAYLOAD.

Returns true if the signature is verified for the header and payload using the specified public key; false if the signature is not verified

`Parameters``:`

certkey_name- identifies the certkey object containing an X.509 certificate holding the RSA public key. Results in an Undef error if the certkey object does not exist or does not contain an X.509 certificate with an RSA public key, if the token is not correctly formatted, or if the verification operation cannot complete.

`Returns:` bool_at

`*JWT_VERIFY_XML` (text_t xml_pkey)

Verifies the signature on the input JSON Web Token (JWT), using the RSA public key supplied by the specified XML element. The token has the format HEADER.PAYLOAD.SIGNATURE where

- HEADER is a base64-encoded JSON structure indicating a signature algorithm and token type, e.g.'{"alg":"RS256","typ":"JWT"}'
- PAYLOAD is a base64-encoded JSON structure with asserted claims, e.g. '{"loggedInAs":"admin","iat":1422779638}'
- SIGNATURE is the base64-encoded bytes for the signature on HEADER.PAYLOAD.

Returns true if the signature is verified for the header and payload using the specified public key; false if the signature is not verified

`Parameters``:`

xml_pkey- an expression that supplies an <RSAKeyValue> element with the public key. Results in an Undef error if the XML element is invalid or does not correctly specify an RSA public key, if the token is not correctly formatted, or if the verification operation cannot complete.

`Returns:` bool_at

`*LENGTH`

Results in a Number Value that is the number of characters (not bytes) in the Text object.

`Returns:` num_at

`*LE` (double_at i)

Returns Boolean TRUE if the double value is lesser than or equal to the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`*LE` (ip_address_at i)

Returns Boolean TRUE if the double value is lesser than or equal to the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`*LE` (num_at i)

Returns Boolean TRUE if the double value is lesser than or equal to the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`*LE` (time_local_at i)

Returns Boolean TRUE if the double value is lesser than or equal to the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`*LE` (time_at i)

Returns Boolean TRUE if the double value is lesser than or equal to the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`*LE` (unsigned_long_at i)

Returns Boolean TRUE if the double value is lesser than or equal to the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`*LE` (text_t s)

Results in Boolean TRUE value if the Text object is less than or equal to the input argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*LOCATION_LONG`

Get the location qualifier from CLIENT.IP.SRC.LOCATION.GET(n) (ISO short name) and then convert it to human readable long name. This conversion is valid only for country names. Correct Country qualifier value (number) in GET(n) is left up to the user as qualifiers are user configurable. Expression example: CLIENT.IP.SRC.LOCATION.GET(1).LOCATION_LONG For example: Data from each expression CLIENT.IP.SRC.LOCATION: NA.US.California.SantaClara.*.* CLIENT.IP.SRC.LOCATION.GET(1): US CLIENT.IP.SRC.LOCATION.GET(1).LOCATION_LONG: United States

`Returns:` text_t

`*LT` (double_at i)

Returns Boolean TRUE if the double value is lesser than the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`*LT` (ip_address_at i)

Returns Boolean TRUE if the double value is lesser than the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`*LT` (num_at i)

Returns Boolean TRUE if the double value is lesser than the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`*LT` (time_local_at i)

Returns Boolean TRUE if the double value is lesser than the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`*LT` (time_at i)

Returns Boolean TRUE if the double value is lesser than the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`*LT` (unsigned_long_at i)

Returns Boolean TRUE if the double value is lesser than the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`*LT` (text_t s)

Results in Boolean TRUE value if the Text object is less than the input argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*MAP_STRING_DEFAULT_TO_KEY` (text_t string_map_name)

Returns the value corresponding to the key in the string map. This is similar to the MAP_STRING method, but if the key is not present then instead of returning a null string, it returns the key itself. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

string_map_name- identifies the string map.

`Returns:` text_t

`*MAP_STRING` (text_t string_map_name)

Returns value corresponding to key in the string map. Key is the string that it is given as input. Text mode IGNORECASE, NOIGNORECASE - controls whether key lookup in string map is case sensitive or not. For example:

- HTTP.REQ.URL.MAP_STRING("url_stringmap") returns value when the value of HTTP.REQ.URL is used as key in the string map whose name is "url_stringmap".
- HTTP.REQ.URL.SET_TEXT_MODE(IGNORECASE). MAP_STRING("url_stringmap") returns value when the value of HTTP.REQ.URL is used as key in the string map whose name is "url_stringmap". Key lookup in this case is done case-insensitively.

`Parameters` (expressions not allowed) `:`

string_map_name- identifies the string map.

`Returns:` text_t

`*MARK_SAFE`

Mark the PIXL expression safe without applying any safe transform.

`Returns:` text_t

`*MAX` (double_at i)

Return the maximum double value after comparing the argument with the current double value.

`Parameters``:`

i- Double

`Returns:` double_at

`*MAX` (ip_address_at i)

Return the maximum double value after comparing the argument with the current double value.

`Parameters``:`

i- Double

`Returns:` double_at

`*MAX` (num_at i)

Return the maximum double value after comparing the argument with the current double value.

`Parameters``:`

i- Double

`Returns:` double_at

`*MAX` (time_local_at i)

Return the maximum double value after comparing the argument with the current double value.

`Parameters``:`

i- Double

`Returns:` double_at

`*MAX` (time_at i)

Return the maximum double value after comparing the argument with the current double value.

`Parameters``:`

i- Double

`Returns:` double_at

`*MAX` (unsigned_long_at i)

Return the maximum double value after comparing the argument with the current double value.

`Parameters``:`

i- Double

`Returns:` double_at

`*MAX` (text_t s)

Compares the string argument with the current string and returns the max string. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*MIN` (double_at i)

Return the minimum double value after comparing the argument with the current double value.

`Parameters``:`

i- Double

`Returns:` double_at

`*MIN` (ip_address_at i)

Return the minimum double value after comparing the argument with the current double value.

`Parameters``:`

i- Double

`Returns:` double_at

`*MIN` (num_at i)

Return the minimum double value after comparing the argument with the current double value.

`Parameters``:`

i- Double

`Returns:` double_at

`*MIN` (time_local_at i)

Return the minimum double value after comparing the argument with the current double value.

`Parameters``:`

i- Double

`Returns:` double_at

`*MIN` (time_at i)

Return the minimum double value after comparing the argument with the current double value.

`Parameters``:`

i- Double

`Returns:` double_at

`*MIN` (unsigned_long_at i)

Return the minimum double value after comparing the argument with the current double value.

`Parameters``:`

i- Double

`Returns:` double_at

`*MIN` (text_t s)

Compares the string argument with the current string and returns the min string. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*MUL` (double_at i)

Return the Double Value after multiplying the argument to the current double value.

`Parameters``:`

i- Double

`Returns:` double_at

`*MUL` (ip_address_at i)

Return the Double Value after multiplying the argument to the current double value.

`Parameters``:`

i- Double

`Returns:` double_at

`*MUL` (num_at i)

Return the Double Value after multiplying the argument to the current double value.

`Parameters``:`

i- Double

`Returns:` double_at

`*MUL` (time_local_at i)

Return the Double Value after multiplying the argument to the current double value.

`Parameters``:`

i- Double

`Returns:` double_at

`*MUL` (time_at i)

Return the Double Value after multiplying the argument to the current double value.

`Parameters``:`

i- Double

`Returns:` double_at

`*MUL` (unsigned_long_at i)

Return the Double Value after multiplying the argument to the current double value.

`Parameters``:`

i- Double

`Returns:` double_at

`*NEG`

Return the Double Value after negating the current double value.

`Returns:` double_at

`*NE` (double_at i)

Returns Boolean TRUE if the double value is not equal to the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`*NE` (ip_address_at i)

Returns Boolean TRUE if the double value is not equal to the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`*NE` (num_at i)

Returns Boolean TRUE if the double value is not equal to the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`*NE` (time_local_at i)

Returns Boolean TRUE if the double value is not equal to the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`*NE` (time_at i)

Returns Boolean TRUE if the double value is not equal to the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`*NE` (unsigned_long_at i)

Returns Boolean TRUE if the double value is not equal to the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`*NE` (text_t s)

Results in Boolean TRUE value if the Text object is not equal to the input argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*NORMALIZE_URL`

Normalize URL. Normalizes a URL by doing "percent" decoding. See the description for URLENCODED in the SET_TEXT_MODE function. This performs the equivalent of SET_TEXT_MODE(URLENCODED).DECODE_USING_TEXT_MODE, except that it does not change the value of the current text mode.

`Returns:` text_t

`*PKEY_ENCRYPT_PEM_NO_PADDING` (text_t pem_pkey)

Encrypts the input text using the RSA public key provided by the PEM string and RSA_NO_PADDING padding method. The input text to be encrypted cannot be longer than the public key length minus 11 bytes for padding. For example, for a 1024-bit (128 byte) key, the input text cannot be longer than 128 - 11 = 117 bytes. An Undef error will occur if the input text is too

long. A null input will also cause an Undef error. Returns the (unencoded binary) encrypted text, which is typically base-64 encoded for use in a message.

`Parameters``:`

pem_pkey- a text expression that supplies a RSA public key in the PEM format. If the text value is not a valid PEM RSA PUBLIC KEY encoding, an Undef error will occur. Example (a 1024-bit public key):

```
"-----BEGIN RSA PUBLIC KEY-----" +

"MIGJAoGBAKl5vgQEj73Kxp+9yn1v5gPR1pnc4oLM2a0kaWwBOsB6rzCIy6znwnvw" +

"CY1xRvQhRlJSAyJbloL7wZFIJ2FOR8Cz+8ZQWXU2syG+udi4EnWqLgFYowF9zK+o" +

"79az597eNPAjsHZ/C2oL/+6qY5a/f1z8bQPrHC4GpFfAEJhh/+NnAgMBAAE=" +

"-----END RSA PUBLIC KEY-----"
```

`Returns:` text_t

`*PKEY_ENCRYPT_PEM` (text_t pem_pkey)

Encrypts the input text using the RSA public key provided by the PEM string and the RSA_PKCS1_PADDING padding method. The input text to be encrypted cannot be longer than the public key length minus 11 bytes for padding. For example, for a 1024-bit (128 byte) key, the input text cannot be longer than 128 - 11 = 117 bytes. An Undef error will occur if the input text is too long. A null input will also cause an Undef error. Returns the (unencoded binary) encrypted text, which is typically base-64 encoded for use in a message.

`Parameters``:`

pem_pkey- a text expression that supplies a RSA public key in the PEM format. If the text value is not a valid PEM RSA PUBLIC KEY encoding, an Undef error will occur. Example (a 1024-bit public key):

```
"-----BEGIN RSA PUBLIC KEY-----" +

"MIGJAoGBAKl5vgQEj73Kxp+9yn1v5gPR1pnc4oLM2a0kaWwBOsB6rzCIy6znwnvw" +

"CY1xRvQhRlJSAyJbloL7wZFIJ2FOR8Cz+8ZQWXU2syG+udi4EnWqLgFYowF9zK+o" +
```

```
"79az597eNPAjsHZ/C2oL/+6qY5a/f1z8bQPrHC4GpFfAEJhh/+NnAgMBAAE=" +

"-----END RSA PUBLIC KEY-----"
```

`Returns:` text_t

`*PKEY_SIGN_CERTKEY` (text_t certkey_name)

Generates a binary digital signature using the SHA-256 message digest function and an RSA private key from the specified SSL certKey object.

`Parameters``:`

certkey_name- identifies the configured certKey object. Results in an Undef error if the certkey object does not exist or does not contain an RSA private key, or if the signing operation cannot complete.

`Returns:` text_t

`*PKEY_SIGN_XML` (text_t xml_pkey)

Generates a binary digital signature using the SHA-256 message digest function and an RSA private key from the specified XML element.

`Parameters``:`

xml_pkey- an expression that supplies an <RSAKeyValue> element with the private key. Example: <RSAKeyValue> <Modulus>qXm+BASPvcrGn73KfW/
mA9HWmdzigszZrSRpbAE6wHqvMIjLrOfCe/
AJjXFG9CFGUlIDIluWgvvBkUgnYU5HwLP7xlBZdTazIb652LgSdaouAVijAX3Mr6jv1rPn3t408COwdn8Lagv/
7qpjlr9/XPxtA+scLgakV8AQmGH/42c=</Modulus> <Exponent>AQAB</Exponent>"zNjysxcIJV/
J9cTpIgPp2/x1IXHT5GTH8OMuNad0qtRSLjU1QYUmmkm9QcJJAN+7h8FEXWGabySUzBrHj/
IEbw==" <DP>QavUDQLLQpnPJXtVAo6CYhxOMCd68mwTxYKKNLjmC0pd54SFHllTLPE1FZU5EjK6q3nCeijonpfH+XX
DP> <DQ>EiXOKouJzzXTQJC3TqomF7Uf81yQNxWumOqnd11kepXgyfMwyqMvLlAGEkNSEF/
Bz18R3Wv+MIZ/IC3nLBt2xQ==</DQ>
<InverseQ>ocuCmz36CP+N2aGqxaU+BKD5+3RLgRq9LFhULEz2jKx0iV9r76jsAxn3sLcTYYO9eqRPy2cz74A
nw==</InverseQ> <D>fTBD773a3GzcmgVdfZlaBLpN1ux2mf5uUVrTUQf7eVFm9egm4/
tzC5A9zjC+I/oscwTH8epL3UfRLdtp05Q6pWfJBXEnGo0QmOFFBK4pLx/
5JJpPGZ69ovDFEVOUHyiCfKE/g97T4WX3us0nFe1272zwGlHarM1YYwvfeE08UdE=</D> </

RSAKeyValue> Results in an Undef error if the XML element is invalid or does not correctly specify an RSA private key, or if the signing operation cannot complete.

`Returns:` text_t

`*PKEY_VERIFY_CERTKEY` (text_t certkey_name, text_t signature)

Verifies if the input text matches the specified signature generated using the SHA-256 messge digest function and the RSA private key associated with the specified RSA public key in the X.509 certificate in the specified certKey object. Returns true if the signature is verified, false otherwise.

`Parameters``:`

certkey_name- identifies the certkey object containing an X.509 certificate holding the RSA public key.

signature- the binary signature. Results in an Undef error if the certkey object does not exist or does not contain an X.509 certificate with an RSA public key, or if the verification operation cannot complete.

`Returns:` bool_at

`*PKEY_VERIFY_XML` (text_t xml_pkey, text_t signature)

Verifies if the input text matches the specified signature generated using the SHA-256 messge digest function and the RSA private key associated with the RSA public key supplied by the specified XML element. Returns true if the signature is verified, false otherwise.

`Parameters``:`

xml_pkey- an expression that supplies an <RSAKeyVAlue> element with the public key. Example: <RSAKeyValue> <Modulus>qXm+BASPvcrGn73KfW/mA9HWmdzigszZrSRpbAE6wHqvMIjLrOfCe/AJjXFG9CFGUlIDIluWgvvBkUgnYU5HwLP7xlBZdTazIb652LgSdaouAVijAX3Mr6jv1rPn3t408COwdn8Lagv/7qpjlr9/XPxtA+scLgakV8AQmGH/42c=</Modulus> <Exponent>AQAB</Exponent> </RSAKeyValue>

signature- the binary signature. Results in an Undef error if the XML element is invalid or does not correctly specify an RSA public key, or if the verification operation cannot complete.

`Returns:` bool_at

`*PREFIX` (`char` c, `uint` i)

Select a prefix of the Text. The selected prefix is the longest prefix that has at most Count (2nd argument) occurrences of character in the 1st argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

c- Character

i- Count

`Returns:` text_t

`*PREFIX` (`uint` i)

Select a prefix of the Text. The length of the prefix is equal to the number in the argument. If there aren't enough characters in the Text object then the entire Text is selected.

`Parameters``:`

i- Prefix Length

`Returns:` text_t

`*REGEX_MATCH` (`re` regex)

Returns TRUE if and only if the text contains at least one match of the regular expression argument. The match may occur anywhere within the text - if you wish to "anchor" this, use "\^" at the start of the regex and/or "$" at the end of the regex.

The regular expression has to be of the format: `re<delimiter>regular expression<same delimiter>`

The regular expression cannot be bigger than 1499 characters.

The regular expression should be acceptable by the PCRE regular expression library. Look at http://www.pcre.org/pcre.txt for documentation on the regular expression syntax. In particular, look at the pcrepattern man page.

There are some differences in the allowed syntax w.r.t PCRE syntax. Backreferences are not allowed. It is recommended not to use recursive regular expressions. The dot metacharacter matches newlines also. Unicode is not supported. SET_TEXT_MODE(IGNORECASE) overrides the (?i) internal option specified in the regular expression.

The PCRE library configuration can be seen in the system log, after executing 'nsapimgr -B" call ns_pixl_regex_show_config()"' at the shell prompt.

Some examples:

- HTTP.REQ.HOSTNAME.REGEX_MATCH(re/\[\[:alpha:\]\]+(abc){2,3}/)
- HTTP.REQ.URL.SET_TEXT_MODE(URLENCODED).REGEX_MATCH(re#(a*b+c*)#)
- HTTP.REQ.URL.REGEX_MATCH(re/a(?i)b/) matches ab and aB
- HTTP.REQ.URL.SET_TEXT_MODE(IGNORECASE).REGEX_MATCH(re/ab/) matches ab, aB, Ab and AB
- HTTP.REQ.BODY.REGEX_MATCH(re/(?ixm) (\^ab (.*) cd$) /) does a case-insensitive, multiline match where the dot metacharacter matches newline also. The regex itself can contain whitespace which will be ignored during the matching (x - extended regex).

This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

regex- Regular Expression

`Returns:` bool_at

`*REGEX_REPLACE` (`re` regex, text_t replacement, replacemode_e mode)

Selects the text that matches the given regular expression argument and replaces it with the the text given in the second argument. The third argument specifies whether the first match is only replaced when multiple matches occur in the text or all matches are replaced. The match may occur anywhere within the text - if you wish to "anchor" this, use "\^" at the start of the regex and/or "$" at the end of the regex. When the regular expression does not match the given string then the same string is returned.

For example: HTTP.RES.BODY(999).REGEX_REPLACE(re!\\bpassword:\\s*\\b!, "password: ***", ALL) will replace all occurrences of "password:" with "password: ***" This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

regex- Regular Expression

replacement- String to replace the match

mode- Mode of replacement

`Returns:` text_t

`*REGEX_SELECT` (`re` regex)

Selects the text that matches the given regular expression argument. The first match is returned when multiple matches occur in the text. The match may occur anywhere within the text - if you wish to "anchor" this, use "\^" at the start of the regex and/or "$" at the end of the regex. When the regular expression does not match the given string, a Text object of length 0 is returned.

For example: HTTP.REQ.HEADER("via").REGEX_SELECT(re!NS-CACHE-\\d\\.\\d:\\s*\\d{1,3}!) will select "NS-CACHE-7.0: 70" This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

regex- Regular Expression

`Returns:` text_t

`*REPEAT` (`uint` i)

Produces a string which contains 'i' sequential copies of the input string.

`Parameters``:`

i- the number of times to repeat the string (0 or more)

`Returns:` text_t

`*SET_CHAR_SET` (charset_e charset)

Set the character set to use for subsequent functions that use text.

`Parameters` (expressions not allowed) `:`

charset- Character Set

`Returns:` double_t

`*SET_TEXT_MODE` (textmode_e mode)

The mode setting of a Text object controls the behavior of many Text operations. The Text mode settings may also control the behavior of some operations in objects (like List) that build upon the Text object. IGNORECASE, NOIGNORECASE - controls whether string comparison is case sensitive or not. URLENCODED - If set then all Text operations are carried out after translating all

%HH or %uHHHH encodings in the underlying byte stream. 1. %HH will be translated to the character Y where HH denotes the ascii value of character Y in hexadecimal. For example, the encoded text "http%3a/.html" will be decoded to "http:/.html" 2. %uWWHH will be translated to the character sequence YZ where WW denotes the ascii value of character Y in hexadecimal and HH denotes the ascii value of character Z in hexadecimal. For example, the encoded text "http%u3a2f.html" and "http%u003a/.html" will both be decoded to"http:/.html" NOURLENCODED - Indicates that no percent encodings are present in the Text object. No percent decoding will be performed on the Text object. PLUS_AS_SPACE - If set then all Text operations are carried out after converting occurrences of the plus character to whitespace. For example, the text "hello+world" will be decoded to "hello world" NO_PLUS_AS_SPACE - If set, then the plus character will not be converted to whitespace in the Text object. BACKSLASH_ENCODED - If set, then all Text operations are carried out after performing the following operations: 1. \\XXX will be translated to the character Y where XXX denotes the ascii value of character Y in octal. The valid range of octal values for this type of encoding is \\0 to \\377. For example, the encoded text "http\\72/.html" and "http\\072/.html" will both be decoded to "http:/.html" 2. \\xHH will be translated to the character Y where HH denotes the ascii value of character Y in hexadecimal. For example, the encoded text "http\\x3a/.html" will be decoded to "http:/.html" 3. \\\\uWWXX will be translated to the character sequence YZ where WW denotes the ascii value of character Y in hexadecimal and XX denotes the ascii value of character Z in hexadecimal. For example, the encoded text "http%u3a2f.html" and "http%u003a/.html" will both be decoded to"http:/.html" 4. Occurences of "\\b", "\\n", "\\t", "\\f" and "\\r" are translated to the corresponding ascii characters. NO_BACKSLASH_ENCODED - If set, then backslash decoding will not be performed on the Text object. BAD_ENCODE_RAISE_UNDEF - If set, then UNDEF is raised if either the URLENCODED or BACKSLASH_ENCODED mode is set and a bad encoding corresponding to the specified encoding mode is encountered. NO_BAD_ENCODE_RAISE_UNDEF - If set, then UNDEF will not be raised when a bad encoding is encountered in the Text object. The Text operations operate on characters (as opposed to operating on bytes). By default a single byte represents a character using the ASCII encoding. But if URLENCODED mode is set then 3 bytes may represent a character. A PREFIX(3) operation will select the first 3 characters in the Text object. That means it may select up to 9 bytes for URLENCODED Text object. In the case of multibyte decodings as a result of %uXXXX or \\\\uXXXX, Text operations which attempt to treat the multiple decoded bytes as distinct characters are not allowed.

`Parameters` (expressions not allowed) `:`

mode- Text Mode

`Returns:` double_t

`*SKIP` (`char` c, `uint` i)

Select the Text after skipping over a prefix of the current Text. The skipped over prefix is the longest prefix that has at most Count (2nd argument) occurrences of character in the 1st argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

c- Character

i- Count

`Returns:` text_t

`*SKIP` (`uint` i)

Select the Text after skipping over a prefix in the current Text. The length of the prefix is equal to the number in the argument. If there aren't enough characters in the Text object then the entire Text is skipped over.

`Parameters` (expressions not allowed) `:`

i- Prefix Length

`Returns:` text_t

`*STARTSWITH_ANY` (text_t patset_name)

Results in Boolean TRUE value if the Text starts with any of the strings that are bound to the patset or dataset named by the string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` bool_at

`*STARTSWITH_INDEX` (text_t patset_name)

Returns the numerical index of the matching string, if the Text starts with any of the strings that are bound to the patset or dataset named by the string argument. Returns 0 if there is no match. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` num_at

`*STARTSWITH` (text_t start)

Results in Boolean TRUE value if a prefix of the Text object matches the string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

start- String

`Returns:` bool_at

`*STRIP_CHARS` (text_t s)

From the selected text remove the characters specified in the string.

For example: Say the selected text is / "foo.xyz=bar" /. Then on executing STRIP_CHARS('.=') or STRIP_CHARS('..=') the selected text will become /fooxyzbar /. Note that repeating character has same effect as it would be if it present only once. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*STRIP_END_CHARS` (text_t s)

Selects the Text after stripping off characters in the end of the current Text object.

For example: Say the selected text is / "foo.xyz=bar" /. Then on executing STRIP_END_CHARS('ar') the selected text will become /foo.xyz=b /. Note that repeating character has same effect as it would be if it present only once. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*STRIP_END_WS`

Selects the Text after stripping off white space in the end of the current Text object.

`Returns:` text_t

`*STRIP_START_CHARS` (text_t s)

Selects the Text after stripping off characters in the beginning of the current Text object.

For example: Say the selected text is / "foo.xyz=bar" /. Then on executing STRIP_START_CHARS('of') the selected text will become /.xyz=bar /. Note that repeating character has same effect as it would be if it present only once. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*STRIP_START_WS`

Selects the Text after stripping off white space in the beginning of the current Text object.

`Returns:` text_t

`*SUBSTR_ANY` (text_t patset_name)

Select any one sub-string that matches any string in the given patset or dataset. The patset cannot have strings longer than 255 characters. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` text_t

`*SUBSTR` (`uint` start, `uint` len)

Select the Text object of the given length at the given offset. Offset it 0 based. If there aren't enough characters after the offset then all the remaining characters are selected.

`Parameters``:`

start- Offset

len- Length

`Returns:` text_t

`*SUBSTR` (text_t s)

Select the first Text object that matches the input string argument. The input string cannot be bigger than 255 characters. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*SUB` (double_at i)

Return the Double Value after subtracting the argument from the current double value.

`Parameters``:`

i- Double

`Returns:` double_at

`*SUB` (ip_address_at i)

Return the Double Value after subtracting the argument from the current double value.

`Parameters``:`

i- Double

`Returns:` double_at

`*SUB` (num_at i)

Return the Double Value after subtracting the argument from the current double value.

`Parameters``:`

i- Double

`Returns:` double_at

`*SUB` (time_local_at i)

Return the Double Value after subtracting the argument from the current double value.

`Parameters``:`

i- Double

`Returns:` double_at

`*SUB` (time_at i)

Return the Double Value after subtracting the argument from the current double value.

`Parameters``:`

i- Double

`Returns:` double_at

`*SUB` (unsigned_long_at i)

Return the Double Value after subtracting the argument from the current double value.

`Parameters``:`

i- Double

`Returns:` double_at

`*SUFFIX` (`char` c, `uint` i)

Select a suffix of the Text. The selected suffix is the longest possible suffix containing at most Count (2nd arg) occurrences of the character in the 1st argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

c- Character

i- Count

`Returns:` text_t

`*SUFFIX` (`uint` i)

Select a suffix of the Text. The length of the suffix is equal to the number in the argument. If there aren't enough characters in the Text object then the entire Text is selected.

`Parameters``:`

i- Suffix Length

`Returns:` text_t

`*TO_LOWER`

Converts the selected text to lower case.

For example, the string "ABCd" is converted to "abcd"

`Returns:` text_t

`*TO_UPPER`

Converts the selected text to upper case.

For example, the string "abcD" is converted to "ABCD"

`Returns:` text_t

`*TRUNCATE` (`char` c, `uint` i)

Select the Text after truncating a suffix from the current Text object. The truncated suffix is the longest possible suffix containing at most Count (2nd arg) occurrences of the character in the 1st argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

c- Character

i- Count

`Returns:` text_t

`*TRUNCATE` (`uint` i)

Select the Text after truncating a suffix of the Text. The length of the suffix truncated is equal to the number in the argument. If there aren't enough characters in the Text then then all the characters are truncated.

`Parameters``:`

i- Suffix Length

`Returns:` text_t

`*TYPECAST_AVP_T`

Convert text_t to avp_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (avp_t : Operations that can be performed on the returned AVPs.

`Note:` An AVP can have multiple instances in a Diameter message. However, the system can access only the first 16 instances.

`Example:`

- To get the first value of AVP code 266 from a request, use: DIAMETER.REQ.AVP(266).VALUE(0).
- To get the fourth value of AVP code 266 from a request, use: DIAMETER.REQ.AVP(266).VALUE(3).
- To check if AVP code 1000 in the response has the vendor-specific bit set, use: DIAMETER.RES.AVP(1000).IS_VENDOR_SPECIFIC.

)

`Returns:` avp_t

`*TYPECAST_AVP_UNUM_T`

Convert text_t to avp_unum_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (avp_unum_t : In Diameter AVP based expressions can be written as DIAMETER.REQ.AVP(<avpcode>). For example Auth-Application-Id AVP (AVP code 258) can be extracted as DIAMETER.REQ.AVP(258) For few of the important AVPs we provide aliases. For example this AVP based expression can also be written as DIAMETER.REQ.AUTH_APPLICATION_ID. This expression returns either a object of class avp_t or returns a numerical value (object of class unsigned_long_at). The numerical value for this object is derived from the value in first instance of the AVP.)

`Returns:` avp_unum_t

`*TYPECAST_BOOL_AT`

Convert text_t to bool_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (bool_at : Boolean Operations)

`Returns:` bool_at

`*TYPECAST_COOKIE_T`

Convert text_t to cookie_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (cookie_t : The HTTP Cookie type provides operations for a cookie as it appears in the Set-Cookie and Set-Cookie2 header. In this type the Name-Value List operations are also available. The first delimiter is = and the element delimiter is ;. Multiple consecutive ; are treated as one. (Same as applying the method IGNORE_EMPTY_ELEMENTS on a Name-Value List.) You can use the Name-value List operations to access cookie attributes. The name comparison for all list operations is case insensitive. In this type Text operations are also available. Each cookie begins with a COOKIE_NAME=COOKIE_VALUE pair followed by zero or more semi-colon separated attribute-value pairs. If an attribute appears more than once in a cookie, the value associated with the first appearance of the attribute is returned.

Format Cookie: Cookie1=Value;Version=decimal;Value;Domain=Value;Path=Value)

`Returns:` cookie_t

`*TYPECAST_DIAMETER_FLAG_T`

Convert text_t to diameter_flag_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (diameter_flag_t : Provides operation to treat the underlying 1 byte as set of bit flags. then set/unset/test/reset_all operations can be done on flag)

`Returns:` diameter_flag_t

`*TYPECAST_DNS_DOMAINNAME_T`

Convert text_t to dns_domainname_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (dns_domainname_t : This object provides operations for parsing the DNS domain name as it appears at various places in the DNS data. The format is abc.foo.com.)

`Returns:` dns_domainname_t

`*TYPECAST_DNS_FLAG_T`

Convert text_t to dns_flag_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (dns_flag_t : Provides operations to test/set/unset a flag in dns header.)

`Returns:` dns_flag_t

`*TYPECAST_DOUBLE_T` (double_format_e format)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error.)

`Parameters` (expressions not allowed) `:`

format- Format

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, double_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, ip_address_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, num_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, time_local_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one

or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, time_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, unsigned_long_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_HTTP_CACHE_CONTROL_T`

Convert text_t to http_cache_control_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_cache_control_t : This object provides for the ability to work on HTTP Cache-Control headers. The name comparison for all list operations is case insensitive.)

`Returns:` http_cache_control_t

`*TYPECAST_HTTP_CONTENT_LENGTH_T`

Convert text_t to http_content_length_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_content_length_t : The HTTP.REQ.CONTENT_LENGTH or HTTP.RES.CONTENT_LENGTH object can be treated as a HTTP Header or as a Number. The numerical value for this object is derived from the value in the last instance of the Content-Length header.)

`Returns:` http_content_length_t

`*TYPECAST_HTTP_COOKIE_T`

Convert text_t to http_cookie_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_cookie_t : This object provides operations for parsing the HTTP cookie header. The name-value pair is derived from the value in the last instance of Cookie header. The format is Cookie : name0=value0; name1=value1; An HTTP Cookie header can have multiple occurrences. COUNT will return a Number containing how many headers of the current type exist. The name comparison for all list operations is case insensitive. The system does not keep track of more than 15 HTTP headers. The result will be undefined if there are more than 15 instances of the header.)

`Returns:` http_cookie_t

`*TYPECAST_HTTP_DATE_T`

Convert text_t to http_date_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_date_t : The HTTP.REQ.DATE or HTTP.RES.DATE object can be treated as a HTTP header or a Time object. The Time value is derived from the value in the last instance of the Date header. The date formats supported are RFC 822 (updated by RFC 1123), RFC 1036 (obsoletes RFC850) and ANSI C asctime() formats.)

`Returns:` http_date_t

`*TYPECAST_HTTP_HEADER_T` (text_t name)

Convert text_t to http_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_header_t : When typecasting a Text object to HTTP Header a header name must be provided.For example: HTTP.REQ.HEADER("MyHdr").TYPECAST_HTTP_HEADER_T("InHdr"))

`Parameters` (expressions not allowed) `:`

name- Header Name

`Returns:` http_header_t

`*TYPECAST_HTTP_HOSTNAME_T`

Convert text_t to http_hostname_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_hostname_t : This object provides operations for parsing the HTTP hostname as it appears at various places in the HTTP protocol data. The format is abc.foo.com:8080.)

`Returns:` http_hostname_t

`*TYPECAST_HTTP_METHOD_T`

Convert text_t to http_method_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_method_t : This object provides Text operations and HTTP Request Method Enum operations on the HTTP request method.)

`Returns:` http_method_t

`*TYPECAST_HTTP_SET_COOKIE_T`

Convert text_t to http_set_cookie_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_set_cookie_t : HTTP.RES.SET_COOKIE provides operations for parsing and operating on the SET-COOKIE header that is present in the HTTP response. HTTP Set-Cookie header supports Text and HTTP Header operations. For most Text operations the value in the last Set-Cookie header is selected. HTTP Set-Cookie header also supports special operations to extract cookies from the response. It is assumed that there will be only one cookie in a Set-Cookie header.)

`Returns:` http_set_cookie_t

`*TYPECAST_HTTP_URL_T`

Convert text_t to http_url_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_url_t : HTTP.REQ.URL provides operations for parsing and operating on the URL that is present in the first line of the HTTP request header. The supported format is \[<protocol>://<hostname>\]<path>?<query>. The Text object backing a HTTP URL object has the Text Mode set to URLENCODED by default.)

`Returns:` http_url_t

`*TYPECAST_HTTP_VERSION_T`

Convert text_t to http_version_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_version_t : HTTP.REQ.VERSION or HTTP.RES.VERSION provide operations to extract HTTP version information.)

`Returns:` http_version_t

`*TYPECAST_IPV6_ADDRESS_AT`

Convert text_t to ipv6_address_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ipv6_address_at : Provides operations for the 128-bit IPv6 address value. Some general information regarding IPv6 expressions: IPv6 PIXL expressions can be combined with other PIXL expressions using the '+' operator. The output is expected to be the concatenation of the string representations of the individual PIXL expressions. No other operator other than '+' is expected to work when any of the operands is an IPv6 PIXL expression. Also, IPv6 PIXL expressions can be combined with any other type of PIXL expression except a PIXL expression that produces a bool result. In other words, if A and/or B are two IPv6 addresses, A+B should result in the string AB. When one of A or B is an IPv6 address, the other can only be a number or a string and not a boolean. Further, when A and/or B is an IPv6 address, the only operator allowed between them is '+'.

Example: Let the client source IPv6 address be ABCD:1234::ABCD. Let the server destination IPv4 address be 10.100.10.100. Then the expression CLIENT.IPV6.SRC + SERVER.IP.DST should produce the output "ABCD:1234::ABCD10.100.10.100". Similarly, CLIENT.IPV6.SRC + 5 should produce the result ABCD:1234::ABCD5)

`Returns:` ipv6_address_at

`*TYPECAST_IPV6_ADDRESS_T`

Convert text_t to ipv6_address_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ipv6_address_t : This object represents an IPv6 address present in the 1000:1001:CD10:0000:0000:89AB:4567:CDEF format.)

`Returns:` ipv6_address_t

`*TYPECAST_IPV6_SUBNET_AT`

Convert text_t to ipv6_subnet_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ipv6_subnet_at : Provides operations for the integral IPv6 subnet address value.)

`Returns:` ipv6_subnet_at

`*TYPECAST_IPV6_SUBNET_T`

Convert text_t to ipv6_subnet_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ipv6_subnet_t : This object represents an IPv6 subnet address present in the 1000:1001:CD10:0000:0000:89AB:4567:CDEF/64 format.)

`Returns:` ipv6_subnet_t

`*TYPECAST_IP_ADDRESS_AT`

Convert text_t to ip_address_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ip_address_at : Provides operations for the 32-bit integral IP address value.)

`Returns:` ip_address_at

`*TYPECAST_IP_ADDRESS_T`

Convert text_t to ip_address_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ip_address_t : Represents an IP address present in the 10.100.200.1 format.)

`Returns:` ip_address_t

`*TYPECAST_IP_OPTIONS_T`

Convert text_t to ip_options_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ip_options_t : IP protocol options)

`Returns:` ip_options_t

`*TYPECAST_IP_OPTIONS_TYPE_T`

Convert text_t to ip_options_type_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ip_options_type_t : IP Options Type)

`Returns:` ip_options_type_t

`*TYPECAST_IP_TOS_T`

Convert text_t to ip_tos_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ip_tos_t : Provides operations to TOS field in IP header.)

`Returns:` ip_tos_t

`*TYPECAST_LIST_T` (`char` sep)

Convert text_t to list_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (list_t : The character separator has to be provided when typecasting a textual context to list type. The current text mode has no effect on the character separator. For example if the current text mode is IGNORECASE and the separator is p then P will not be treated as a separator.)

`Parameters` (expressions not allowed) `:`

sep- Separator

`Returns:` list_t

`*TYPECAST_MAC_ADDRESS_AT`

Convert text_t to mac_address_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (mac_address_at : Provides operations for the 48-bit MAC address value.)

`Returns:` mac_address_at

`*TYPECAST_MAC_ADDRESS_T`

Convert text_t to mac_address_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (mac_address_t : Represents a MAC address present in the 12:34:56:78:9a:bc format.)

`Returns:` mac_address_t

`*TYPECAST_NUM_AT`

Typecast the Double Value to a Number value.

`Returns:` num_at

`*TYPECAST_NUM_T` (num_format_e format)

Convert text_t to num_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (num_t : Treat the underlying text as a Number in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error.)

`Parameters` (expressions not allowed) `:`

format- Format

`Returns:` num_t

`*TYPECAST_NUM_T` (num_format_e format, num_at default_value)

Convert text_t to num_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (num_t : Treat the underlying text as a Number in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` num_t

`*TYPECAST_NVLIST_T` (`char` sep1, `char` sep2)

Convert text_t to nvlist_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (nvlist_t : Two character delimiters have to be provided when typecasting a Text object to a Name-Value List. The first delimited separates the name from the value. The second delimiter separates list items. For example typecast_nvlist_t('=', '&') handles a URL query string. The Text Mode has no effect on the character delimiters. For example if the current text mode is IGNORECASE and a delimiter is p then P will not be treated as a delimiter.)

`Parameters` (expressions not allowed) `:`

sep1- delimiter1

sep2- delimiter2

`Returns:` nvlist_t

`*TYPECAST_NVLIST_T` (`char` sep1, `char` sep2, `char` quote)

Convert text_t to nvlist_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (nvlist_t : Two character delimiters and quote-character have to be provided when typecasting a Text object to a Name-Value List that supports quote-character. The first delimited separates the name from the value. The second delimiter separates list items. The third value specifies the quote character. For example typecast_nvlist_t('=', ';', "") handles a name-value list separated by semi-colons that allows quoting. The quote-character specifies that the value can occur within the quotes and the delimiters within the quote-characters should not be taken into account. The Text Mode has no effect on the character delimiters. For example if the current text mode is IGNORECASE and a delimiter is p then P will not be treated as a delimiter.)

`Parameters` (expressions not allowed) `:`

sep1- delimiter1

sep2- delimiter2

quote- quote-character.

`Returns:` nvlist_t

`*TYPECAST_PROTOCOL_BUFFER_T`

Convert text_t to protocol_buffer_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (protocol_buffer_t : gRPC Protocol Buffers interface)

`Returns:` protocol_buffer_t

`*TYPECAST_RADIUS_AVP_T`

Convert text_t to radius_avp_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (radius_avp_t : Operations that can be performed on the returned AVPs.

`Note:` An AVP can have multiple instances in a radius message. However, the system can access only the first 16 instances.

`Example:`

- To get the first value of AVP code 26 from a request, use: radius.REQ.AVP(26).VALUE(0).
- To get the fourth value of AVP code 26 from a request, use: radius.REQ.AVP(26).VALUE(3).

)

`Returns:` radius_avp_t

`*TYPECAST_RADIUS_AVP_VALUE_T`

Convert text_t to radius_avp_value_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (radius_avp_value_t : Provides operations to typecast RADIUS AVP value to Integer value or IP Address.)

`Returns:` radius_avp_value_t

`*TYPECAST_SEQ_TEXT_T`

Convert text_t to seq_text_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (seq_text_t : Represents the Text Sequence class.)

`Returns:` seq_text_t

`*TYPECAST_SERVICEPATH_T`

Convert text_t to servicepath_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (servicepath_t : Operations that can be performed on the service path.

`Example:`

- To get the name of the service path applicable to current subscriber, use: SUBSCRIBER.SERVICEPATH

- To determine If the service function is the next in the service path applicable to scubscriber, use: SUBSCRIBER.SERVICEPATH.IS_NEXT().

)

`Returns:` servicepath_t

`*TYPECAST_SIP_CALLID_HEADER_T`

Convert text_t to sip_callid_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_callid_header_t : This object provides operations for parsing the SIP callid header.)

`Returns:` sip_callid_header_t

`*TYPECAST_SIP_CONTENT_LENGTH_T`

Convert text_t to sip_content_length_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_content_length_t : The SIP.REQ.CONTENT_LENGTH or SIP.RES.CONTENT_LENGTH object can be treated as a SIP Header or as a Number. The numerical value for this object is derived from the value in the last instance of the Content-Length header.)

`Returns:` sip_content_length_t

`*TYPECAST_SIP_FROM_HEADER_T`

Convert text_t to sip_from_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_from_header_t : This object provides operations for parsing the SIP From header.)

`Returns:` sip_from_header_t

`*TYPECAST_SIP_HEADER_T` (text_t name)

Convert text_t to sip_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_header_t : When typecasting a Text object to SIP Header a header name must be provided.For example: SIP.REQ.HEADER("MyHdr").TYPECAST_SIP_HEADER_T("InHdr"))

`Parameters` (expressions not allowed) `:`

name- Header Name

`Returns:` sip_header_t

`*TYPECAST_SIP_HOSTNAME_T`

Convert text_t to sip_hostname_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_hostname_t : This object provides operations for parsing the SIP hostname as it appears at various places in the SIP protocol data. The format is abc.foo.com:5060.)

`Returns:` sip_hostname_t

`*TYPECAST_SIP_METHOD_T`

Convert text_t to sip_method_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_method_t : This object provides Text operations and SIP Request Method Enum operations on the SIP request method.)

`Returns:` sip_method_t

`*TYPECAST_SIP_TO_HEADER_T`

Convert text_t to sip_to_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_to_header_t : This object provides operations for parsing the SIP From header.)

`Returns:` sip_to_header_t

`*TYPECAST_SIP_URL_T`

Convert text_t to sip_url_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_url_t : SIP.REQ.URL provides operations for parsing and operating on the URL that is present in the first line of the SIP request header. The supported format is \[<protocol>://<hostname>\]<path>?<query>. The Text object backing a SIP URL object has the Text Mode set to URLENCODED by default.)

`Returns:` sip_url_t

`*TYPECAST_SIP_VERSION_T`

Convert text_t to sip_version_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_version_t : SIP.REQ.VERSION or SIP.RES.VERSION provide operations to extract SIP version information.)

`Returns:` sip_version_t

`*TYPECAST_SIP_VIA_HEADER_T`

Convert text_t to sip_via_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_via_header_t : This object provides operations for parsing the SIP Via header.)

`Returns:` sip_via_header_t

`*TYPECAST_SSLVPN_MODE_T`

Convert text_t to sslvpn_mode_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sslvpn_mode_t : This object provides Text operations and SSLVPN Mode Enum operations on the SSLVPN request method.)

`Returns:` sslvpn_mode_t

`*TYPECAST_SSL_TEXT_T` (text_t name)

Convert text_t to ssl_text_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ssl_text_t : Treat the underlying text object as SSL Text.)

`Parameters` (expressions not allowed) `:`

name- Name

`Returns:` ssl_text_t

`*TYPECAST_TCP_OPTIONS_T`

Convert text_t to tcp_options_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (tcp_options_t : TCP Protocol Options)

`Returns:` tcp_options_t

`*TYPECAST_TCP_OPTIONS_TYPE_T`

Convert text_t to tcp_options_type_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (tcp_options_type_t : TCP Protocol Options Type)

`Returns:` tcp_options_type_t

`*TYPECAST_TCP_REPEATER_OPTION_T`

Convert text_t to tcp_repeater_option_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (tcp_repeater_option_t : TCP Protocol Option : Repeater)

`Returns:` tcp_repeater_option_t

`*TYPECAST_TIME_AT`

Convert text_t to time_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (time_at : Treats a number value as number of seconds since GMT Jan 1 1970 0h 0m 0s.)

`Returns:` time_at

`*TYPECAST_TIME_LOCAL_AT`

Convert text_t to time_local_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (time_local_at : Treats a number value as number of seconds since GMT Jan 1 1970 0h 0m 0s as adjsuted for the local time zone.)

`Returns:` time_local_at

`*TYPECAST_TIME_T`

Convert text_t to time_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (time_t : This object treats a Text object as a date string. The formats supported are

1\. RFC822 :: Sun, 06 Nov 1994 08:49:37 GMT 2\. RFC850 :: Sunday, 06-Nov-94 08:49:37 GMT 3\. ASCTIME :: Sun Nov 6 08:49:37 1994 4\. ASCTIME like :: Sun Nov 6 08:49:37 1994 5\. ASCTIME like :: Sun Nov 06 08:49:37 1994 6\. Http Set-Cookie Expiry date :: Sun, 06-Nov-1994 08:49:37 GMT)

`Returns:` time_t

`*TYPECAST_UNSIGNED_LONG_AT`

Typecast the Double Value to a Unsigned Long value.

`Returns:` unsigned_long_at

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error.)

`Parameters` (expressions not allowed) `:`

format- Format

`Returns:` unsigned_long_t

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format, ip_address_at default_value)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` unsigned_long_t

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format, unsigned_long_at default_value)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining

characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` unsigned_long_t

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format, num_at default_value)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` unsigned_long_t

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format, time_local_at default_value)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` unsigned_long_t

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format, time_at default_value)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` unsigned_long_t

`*TYPECAST_UNUM_TEXT_T`

Convert text_t to unum_text_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unum_text_t : Provides operations to treat the underlying OctectString as Binary String or unsigned long value .)

`Returns:` unum_text_t

`*TYPECAST_URL_CATEGORY_T`

Convert text_t to url_category_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (url_category_t : Retrieves URL category and attributes from an URL)

`Returns:` url_category_t

`*TYPECAST_VENDOR_SPEC_APPID_AVP_T`

Convert text_t to vendor_spec_appid_avp_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (vendor_spec_appid_avp_t : Retrieves AVPs that are nested in the grouped AVP Vendor-Specific-Application-Id (code 260). The nested AVPs are:

- Vendor-Id
- Auth-Application-Id
- Acct-Application-Id

For example, to retrieve the Auth-Application-Id AVP from the Vendor-Specific-Application-Id AVP:

- For requests: DIAMETER.REQ.VENDOR_SPECIFIC_APPLICATION_ID.AUTH_APPLICATION_ID
- For responses: DIAMETER.RES.VENDOR_SPECIFIC_APPLICATION_ID.AUTH_APPLICATION_ID

)

`Returns:` vendor_spec_appid_avp_t

`*TYPECAST_VENDOR_SPEC_RADIUS_AVP_T`

Convert text_t to vendor_spec_radius_avp_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (vendor_spec_radius_avp_t :

- Vendor-Id

To retrieve the Vendor-Id from the Vendor-Specific AVP:

- RADIUS.REQ.VENDOR_SPECIFIC.VENDORID

)

`Returns:` vendor_spec_radius_avp_t

`*UNQUOTE` (`char` c)

If selected text is quoted by character c, Remove character c from beginning and end.

For example: Say the selected text is / "foo xyz bar " /. Then on executing UNQUOTE("") the selected text will become /foo xyz bar / This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

c- Character

`Returns:` text_t

`*URLSET_MATCHES_ANY` (text_t urlset_name)

Results in Boolean TRUE value if and only if the Text matches any of the patterns that are specified in the urlset named by the string argument. The matching is case-insensitive for domains, but case-sensitive for paths. For example:

- HTTP.REQ.HOST.APPEND(HTTP.REQ.URL).URLSET_MATCHES_ANY("urlset_forbidden") returns true when the combined domain and URL matches any pattern in the urlset whose name is "urlset_forbidden".

`Parameters` (expressions not allowed) `:`

urlset_name- urlset name

`Returns:` bool_at

`*URL_CATEGORIZE` (`uint` min_reputation, `uint` max_reputation)

Returns the URL category for the supplied URL with the given minimum and maximum reputation score. Where a score of 5 is most risky and 1 is least risky. If either score is set to 0, that bound would be ignored. By specifying the reputation scores, the function will returned the category with the highest score (most risky) based on the bounds. If there was an error getting the category or if the URL is invalid then it will result in an Undef error. For example: HTTP.REQ.HOST.APPEND(HTTP.REQ.URL).URL_CATEGORIZE(0, 0) returns value when the combined domain and URL is looked up for the URL category with the highest reputation score (most risky).

`Parameters` (expressions not allowed) `:`

min_reputation- Minimum reputation score of URL category

max_reputation- Maximum reputation score of URL category

`Returns:` url_category_t

`*URL_RESERVED_CHARS_SAFE`

Converts URL reserved characters to corresponding '%XX' values and retains the rest. This is a read only operation.

```
Based on RFC3986, following are considered URL unreserved characters:

    Alpha-numeric characters: a-z, A-Z, 0-9

    Hyphen and underscore: "-", "_"

    Dot: "."

    Tilde: "~"
```

The rest are converted to %XX encoding, 'XX' is the hex-based representation of the input character. If the requirement is to encode all but URL safe characters, please consider using HTTP_URL_SAFE method.

`Returns:` text_t

`*XML_DECRYPT` (text_t certKeyName)

Decrypt the selected content, which was encrypted using the W3C XML Encryption standard.

`Parameters` (expressions not allowed) `:`

certKeyName- identifies the certkey object containing the RSA private key to be used to decrypt the bulk encryption key in the selected EncryptedData element.

`Returns:` text_t

`*XML_ENCRYPT` (text_t certKeyName, encrypt_method_e method)

Encrypt the selected cleartext using the W3C XML Encryption standard.

`Parameters` (expressions not allowed) `:`

certKeyName- identifies the certkey object containing an X.509 certificate with the RSA public key to be used to encrypt the generated bulk encryption key. Note that the certKey object need not, and usually will not, include the associated RSA private key.

method- specifies the bulk encryption method (rc4, des3, aes128, aes192, or aes256) used to encrypt the content.

`Returns:` text_t

`*XML_ENCRYPT` (text_t certKeyName, encrypt_method_e method, `uint` flags)

Encrypt the selected cleartext using the W3C XML Encryption standard.

`Parameters` (expressions not allowed) `:`

certKeyName- identifies the certkey object containing an X.509 certificate with the RSA public key to be used to encrypt the generated bulk encryption key. Note that the certKey object need not, and usually will not, include the associated RSA private key.

method- specifies the bulk encryption method (rc4, des3, aes128, aes192, or aes256) used to encrypt the content.

flags- optional bit mask to specify optional elements in the EncryptedData element. These are hints to tell the receiver what private key to use to decrypt the bulk encryption key, providing information from the certKey's X.509 certificate.

- 1 - include a KeyName element with the certKeyName;
- 2 - include a KeyValue element with the RSA public key from the certificate;
- 4 - include an X509IssuerSerial element with the certificate serial number and issuer DN;
- 8 - include an X509SubjectName element with the certificate subject DN;
- 16 - include an X509Certificate element with the entire certificate;

`Returns:` text_t

`*XPATH_HTML_WITH_MARKUP` (`xpath_str` xpathex)

Applies an XPath expression to the DOM for an HTML document and returns the selected node-set or string, including markup like element tags. node-sets are converted to strings using the standard XPath string conversion routine. The selected portion of the document can be used as the target for rewrite actions.

Examples: HTTP.REQ.BODY(1000).XPATH_HTML_WITH_MARKUP(xp%//md/head/title%) returns the <title> element in the document's <head> This can be used in a rewrite action to replace or delete the <title> element.

`Parameters` (expressions not allowed) `:`

xpathex- XPath Expression

`Returns:` text_t

`*XPATH_HTML` (`xpath_bool` xpathex)

Applies an XPath expression to the DOM for an HTML document and a boolean value.

Examples: HTTP.RES.BODY(1000).XPATH_HTML(xp%boolean(/md/head/meta)%) returns true if the <meta> element exists as a child of <head> element.

`Parameters` (expressions not allowed) `:`

xpathex- XPath Expression

`Returns:` bool_at

`*XPATH_HTML` (`xpath_double` xpathex)

Applies an XPath expression to the DOM for an HTML document and a double value.

Examples: HTTP.RES.BODY(1000).XPATH_HTML(xp%number(//video/@height)%) returns the numeric value of the height attribute of the first <video> element.

`Parameters` (expressions not allowed) `:`

xpathex- XPath Expression

`Returns:` double_at

`*XPATH_HTML` (`xpath_str` xpathex)

Applies an XPath expression to the DOM for an HTML document and returns the selected node-set or string. node-sets are converted to strings using the standard XPath string conversion routine.

Examples: HTTP.REQ.BODY(1000).XPATH_HTML(xp%//img/@src%) returns the string value of the src attribute of the first

ENCRYPT_METHOD_E

Defines the encryption methods allowed in XML_ENCRYPT().

Enumerations

RC4

DES3

AES128

AES192

AES256

ENDIAN_E

Endianness Enum

Enumerations

LITTLE_ENDIAN

BIG_ENDIAN

ERROR_CATEGORY_E

This object represents one of the error categories.

Enumerations

ERR_AAA_GENERIC

This category identifies the scenario when a AAA submodule sends a legacy error number

ERR_AAA_ALLOC

This category identifies all memory allocation issue while processing AAA traffic.

ERR_AAA_C2C

This category of errors identifies the inter-node communication failures that happen while processing AAA traffic.

ERR_AAA_POLICY

This category of errors identifies the failure in policy subsystem while evaluation of policies.

ERR_AAA_CONFIG

This category of errors identifies all configuration issues while processing AAA traffic.

ERR_AAA_IIP

This category of errors identifies the issues while allocating intranet IP to a client.

ERR_AAA_AUTHN

This category of errors identifies the errors AAA module encounters while handling client authentication.

ERR_AAA_REASSEMBLY

This category of errors identifies the errors when AAA module tries to accumulate the post data.

ERR_AAA_NOSERVICE

This category of errors holds all the cases where AAA module fails to establish backend server connection.

ERR_AAA_UNAUTHORIZED

This error denotes a failed access to a resource

ERR_AAA_BAD_REQUEST

This error is set when AAA module sees a malformed message

ERR_AAA_PAGE_NOT_FOUND

This error is set when a request for a non-existent page is seen by AAA module

ERR_UNKNOWN

This category of errors is for all such errors for which category is unknown.

ERR_AAA_LOGIN_ATTEMPTS

This category of errors encompasses failures due to exceeding login attempts.

ERR_AAA_SAML

This category of errors represents all errors while processing SAML (Secure Assertion Markup Language) messages.

ERR_AAA_KERBEROS

This category of errors represents all errors while processing Kerberos messages.

AAA_LOGIN_REDIRECT

This category of errors represents all return codes while redirecting user for login.

This topic lists the expressions that are provided by this class.

`EQ` (error_category_e e)

The result is Boolean TRUE if the input argument is equal to the error presented by this object.

`Parameters` (expressions not allowed) `:`

e- Error enumeration

`Returns:` bool_at

`NE` (error_category_e e)

The result is Boolean TRUE if the input argument is not equal to the error presented by this object.

`Parameters` (expressions not allowed) `:`

e- Error enumeration

`Returns:` bool_at

ERROR_T

This object represents Error encountered while processing the last operation.

This topic lists the expressions that are provided by this class.

- `CATEGORY`

  Returns the error category.

`Returns:` error_category_e

ETHER_REQ_PROTOCOL_T

Provides access to MAC Address in Ethernet Requests.

This topic lists the expressions that are provided by this class.

- `DSTMAC`

  Returns MAC address present in the destination field of the Ethernet header. All MAC addresses are given as colon-delimited hexadecimal codes in the format ##:##:##:##:##:##. Valid values for each # include numbers 0-9 and letters A through F.

`Returns:` mac_address_at

- `ETHERTYPE`

  Returns the EtherType of the current Ethernet frame.

`Returns:` ether_type_t

- `SRCMAC`

  Returns MAC address present in the source field of the Ethernet header. All MAC addresses are given as colon-delimited hexadecimal codes in the format ##:##:##:##:##:##. Valid values for each # include numbers 0-9 and letters A through F.

`Returns:` mac_address_at

ETHER_RES_PROTOCOL_T

Provides access to MAC Address in Ethernet Response.

This topic lists the expressions that are provided by this class.

- `DSTMAC`

  Returns MAC address present in the destination field of the Ethernet header

`Returns:` mac_address_at

- `ETHERTYPE`

  Returns the EtherType of the current Ethernet frame.

`Returns:` ether_type_t

- `SRCMAC`

  Returns MAC address present in the source field of the Ethernet header

`Returns:` mac_address_at

ETHER_TYPE_E

This object represents one of the ether types.

Enumerations

PUP

IPV4

ARP

REVARP

IPV6

VLAN

ETHERTYPE_UNKNOWN

This topic lists the expressions that are provided by this class.

`EQ` (ether_type_e ethertype)

The result is Boolean TRUE if the input argument is equal to the ethertype represented by this object.

`Parameters` (expressions not allowed) `:`

ethertype- EtherType

`Returns:` bool_at

`NE` (ether_type_e ethertype)

The result is Boolean TRUE if the input argument is not equal to the ethertype represented by this object.

`Parameters` (expressions not allowed) `:`

ethertype- EtherType

`Returns:` bool_at

ETHER_TYPE_T

This object provides Num operations and EtherType Enum operations on the EtherType.

This topic lists the expressions that are provided by this class.

`*Note` *: Expressions with the * symbol are inherited / promoted from ether_type_e num_at

- `TYPECAST_NUM_AT`

  Convert ether_type_t to num_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (num_at : Number Value)

`Returns:` num_at

`*ABS`

Return the absolute value of the number.

`Returns:` num_at

`*ADD` (double_at i)

Return the Double Value after adding the argument to the current double value.

`Parameters``:`

i- Double

`Returns:` double_at

`*ADD` (ip_address_at i)

Return the Unsigned Long after adding the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*ADD` (unsigned_long_at i)

Return the Unsigned Long after adding the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*ADD` (num_at i)

Return the Number Value after adding the argument to the current number value.

`Parameters``:`

i- Number

`Returns:` num_at

`*ADD` (time_local_at i)

Return the Unsigned Long after adding the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*ADD` (time_at i)

Return the Unsigned Long after adding the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*APPEND` (text_t str)

Appends the given string to the string representation of the current number.

`Parameters``:`

str- the string to append.

`Returns:` text_t

`*AS_MICROSEC_STR`

Returns the current system time in the following format Format: Wday, day Month year hh:mm:ss.ffffff GMT ffffff represents microseconds Examples:

Mon, 05 Mar 2018 10:23:36.568419 GMT

`Returns:` text_t

`*AS_MILLISEC_STR`

Returns the current system time in the following format Format: Wday, day Month year hh:mm:ss.fff GMT fff represents milliseconds Examples:

Mon, 05 Mar 2018 10:23:36.568 GMT

`Returns:` text_t

`*AS_NANOSEC_STR`

Returns the current system time in the following format Format: Wday, day Month year hh:mm:ss.fffffffff GMT fffffffff represents nanoseconds Accuracy may be at larger granularity than nanosecond resolution. Examples:

Mon, 05 Mar 2018 10:23:36.568419567 GMT

`Returns:` text_t

`*BETWEEN` (double_at i, double_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (double_at i, ip_address_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (double_at i, unsigned_long_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (ip_address_at i, double_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (ip_address_at i, ip_address_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (ip_address_at i, unsigned_long_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (unsigned_long_at i, double_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (unsigned_long_at i, ip_address_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (unsigned_long_at i, unsigned_long_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (double_at i, num_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (ip_address_at i, num_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (unsigned_long_at i, num_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (double_at i, time_local_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (ip_address_at i, time_local_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (unsigned_long_at i, time_local_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (double_at i, time_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (ip_address_at i, time_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (unsigned_long_at i, time_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (num_at i, double_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (num_at i, ip_address_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (num_at i, unsigned_long_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (num_at i, num_at j)

Returns Boolean TRUE if the number value is greater than or equal to the Lower argument and the number value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (num_at i, time_local_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (num_at i, time_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (time_local_at i, double_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (time_local_at i, ip_address_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (time_local_at i, unsigned_long_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (time_local_at i, num_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (time_local_at i, time_local_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (time_local_at i, time_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (time_at i, double_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (time_at i, ip_address_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (time_at i, unsigned_long_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (time_at i, num_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (time_at i, time_local_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (time_at i, time_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BITAND` (ip_address_at i)

Return the Unsigned Long Value after bitwise ANDing the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*BITAND` (unsigned_long_at i)

Return the Unsigned Long Value after bitwise ANDing the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*BITAND` (num_at i)

Return the Number Value after bitwise ANDing the argument to the current number value.

`Parameters``:`

i- Number

`Returns:` num_at

`*BITAND` (time_local_at i)

Return the Unsigned Long Value after bitwise ANDing the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*BITAND` (time_at i)

Return the Unsigned Long Value after bitwise ANDing the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*BITNEG`

Return the Number Value after bitwise negating the current number value.

`Returns:` num_at

`*BITOR` (ip_address_at i)

Return the Unsigned Long Value after bitwise ORing the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*BITOR` (unsigned_long_at i)

Return the Unsigned Long Value after bitwise ORing the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*BITOR` (num_at i)

Return the Number Value after bitwise ORing the argument to the current number value.

`Parameters``:`

i- Number

`Returns:` num_at

`*BITOR` (time_local_at i)

Return the Unsigned Long Value after bitwise ORing the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*BITOR` (time_at i)

Return the Unsigned Long Value after bitwise ORing the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*BITXOR` (ip_address_at i)

Return the Unsigned Long Value after bitwise XORing the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*BITXOR` (unsigned_long_at i)

Return the Unsigned Long Value after bitwise XORing the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*BITXOR` (num_at i)

Return the Number Value after bitwise XORing the argument to the current number value.

`Parameters``:`

i- Number

`Returns:` num_at

`*BITXOR` (time_local_at i)

Return the Unsigned Long Value after bitwise XORing the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*BITXOR` (time_at i)

Return the Unsigned Long Value after bitwise XORing the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*DIV` (double_at i)

Return the Double Value after dividing the current double value by the argument.

`Parameters``:`

i- Double

`Returns:` double_at

`*DIV` (ip_address_at i)

Return the Unsigned Long Value after dividing the current unsigned long value by the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*DIV` (unsigned_long_at i)

Return the Unsigned Long Value after dividing the current unsigned long value by the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*DIV` (num_at i)

Return the Number Value after dividing the current number value by the argument.

`Parameters``:`

i- Number

`Returns:` num_at

`*DIV` (time_local_at i)

Return the Unsigned Long Value after dividing the current unsigned long value by the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*DIV` (time_at i)

Return the Unsigned Long Value after dividing the current unsigned long value by the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*EQ` (ether_type_e ethertype)

The result is Boolean TRUE if the input argument is equal to the ethertype represented by this object.

`Parameters` (expressions not allowed)`:`

ethertype- EtherType

`Returns:` bool_at

`*EQ` (double_at i)

Returns Boolean TRUE if the double value is equal to the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`*EQ` (ip_address_at i)

Returns Boolean TRUE if the unsigned long is equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*EQ` (unsigned_long_at i)

Returns Boolean TRUE if the unsigned long is equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*EQ` (num_at i)

Returns Boolean TRUE if the number value is equal to the argument.

`Parameters``:`

i- Number

`Returns:` bool_at

`*EQ` (time_local_at i)

Returns Boolean TRUE if the unsigned long is equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*EQ` (time_at i)

Returns Boolean TRUE if the unsigned long is equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*GE` (double_at i)

Returns Boolean TRUE if the double value is greater than or equal to the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`*GE` (ip_address_at i)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*GE` (unsigned_long_at i)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*GE` (num_at i)

Returns Boolean TRUE if the number value is greater than or equal to the argument.

`Parameters``:`

i- Number

`Returns:` bool_at

`*GE` (time_local_at i)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*GE` (time_at i)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*GT` (double_at i)

Returns Boolean TRUE if the double value is greater than the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`*GT` (ip_address_at i)

Returns Boolean TRUE if the unsigned long value is greater than the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*GT` (unsigned_long_at i)

Returns Boolean TRUE if the unsigned long value is greater than the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*GT` (num_at i)

Returns Boolean TRUE if the number value is greater than the argument.

`Parameters``:`

i- Number

`Returns:` bool_at

`*GT` (time_local_at i)

Returns Boolean TRUE if the unsigned long value is greater than the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*GT` (time_at i)

Returns Boolean TRUE if the unsigned long value is greater than the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*LE` (double_at i)

Returns Boolean TRUE if the double value is lesser than or equal to the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`*LE` (ip_address_at i)

Returns Boolean TRUE if the unsigned long value is lesser than or equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*LE` (unsigned_long_at i)

Returns Boolean TRUE if the unsigned long value is lesser than or equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*LE` (num_at i)

Returns Boolean TRUE if the number value is lesser than or equal to the argument.

`Parameters``:`

i- Number

`Returns:` bool_at

`*LE` (time_local_at i)

Returns Boolean TRUE if the unsigned long value is lesser than or equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*LE` (time_at i)

Returns Boolean TRUE if the unsigned long value is lesser than or equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*LSHIFT` (`uint` i)

Return the Number Value after bitwise left shifting the current number value by the argument number of bits. Note that the number of bits shifted is i modulo 32. For example, let HTTP.REQ.URL.LENGTH be 4. Then, HTTP.REQ.URL.LENGTH.LSHIFT(1) = HTTP.REQ.URL.LENGTH.LSHIFT(33) = 8, since 33 on division by 32 yields a remainder of 1.

`Parameters``:`

i- Left Shift Length

`Returns:` num_at

`*LT` (double_at i)

Returns Boolean TRUE if the double value is lesser than the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`*LT` (ip_address_at i)

Returns Boolean TRUE if the unsigned long value is lesser than the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*LT` (unsigned_long_at i)

Returns Boolean TRUE if the unsigned long value is lesser than the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*LT` (num_at i)

Returns Boolean TRUE if the number value is lesser than the argument.

`Parameters``:`

i- Number

`Returns:` bool_at

`*LT` (time_local_at i)

Returns Boolean TRUE if the unsigned long value is lesser than the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*LT` (time_at i)

Returns Boolean TRUE if the unsigned long value is lesser than the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*MAX` (double_at i)

Return the maximum double value after comparing the argument with the current double value.

`Parameters``:`

i- Double

`Returns:` double_at

`*MAX` (ip_address_at i)

Return the maximum unsigned long value after comparing the argument value to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MAX` (unsigned_long_at i)

Return the maximum unsigned long value after comparing the argument value to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MAX` (num_at i)

Return the maximum value after comparing the argument with the current number value.

`Parameters``:`

i- Number

`Returns:` num_at

`*MAX` (time_local_at i)

Return the maximum unsigned long value after comparing the argument value to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MAX` (time_at i)

Return the maximum unsigned long value after comparing the argument value to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MIN` (double_at i)

Return the minimum double value after comparing the argument with the current double value.

`Parameters``:`

i- Double

`Returns:` double_at

`*MIN` (ip_address_at i)

Return the minimum unsigned long value after comparing the argument value to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MIN` (unsigned_long_at i)

Return the minimum unsigned long value after comparing the argument value to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MIN` (num_at i)

Return the minimum value after comparing the argument with the current number value.

`Parameters``:`

i- Number

`Returns:` num_at

`*MIN` (time_local_at i)

Return the minimum unsigned long value after comparing the argument value to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MIN` (time_at i)

Return the minimum unsigned long value after comparing the argument value to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MOD` (ip_address_at i)

Return the Unsigned Long Value that is the renaminder after dividing the current unsigned long value by the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MOD` (unsigned_long_at i)

Return the Unsigned Long Value that is the renaminder after dividing the current unsigned long value by the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MOD` (num_at i)

Return the Number Value that is the renaminder after dividing the current number value by the argument.

`Parameters``:`

i- Number

`Returns:` num_at

`*MOD` (time_local_at i)

Return the Unsigned Long Value that is the renaminder after dividing the current unsigned long value by the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MOD` (time_at i)

Return the Unsigned Long Value that is the renaminder after dividing the current unsigned long value by the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MUL` (double_at i)

Return the Double Value after multiplying the argument to the current double value.

`Parameters``:`

i- Double

`Returns:` double_at

`*MUL` (ip_address_at i)

Return the Unsigned Long Value after multiplying the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MUL` (unsigned_long_at i)

Return the Unsigned Long Value after multiplying the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MUL` (num_at i)

Return the Number Value after multiplying the argument to the current number value.

`Parameters``:`

i- Number

`Returns:` num_at

`*MUL` (time_local_at i)

Return the Unsigned Long Value after multiplying the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MUL` (time_at i)

Return the Unsigned Long Value after multiplying the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*NEG`

Return the Number Value after negating the current number value.

`Returns:` num_at

`*NE` (ether_type_e ethertype)

The result is Boolean TRUE if the input argument is not equal to the ethertype represented by this object.

`Parameters` (expressions not allowed) `:`

ethertype- EtherType

`Returns:` bool_at

`*NE` (double_at i)

Returns Boolean TRUE if the double value is not equal to the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`*NE` (ip_address_at i)

Returns Boolean TRUE if the unsigned long value is not equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*NE` (unsigned_long_at i)

Returns Boolean TRUE if the unsigned long value is not equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*NE` (num_at i)

Returns Boolean TRUE if the number value is not equal to the argument.

`Parameters``:`

i- Number

`Returns:` bool_at

`*NE` (time_local_at i)

Returns Boolean TRUE if the unsigned long value is not equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*NE` (time_at i)

Returns Boolean TRUE if the unsigned long value is not equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*RSHIFT` (`uint` i)

Return the Number Value after bitwise right shifting the current number value by the argument number of bits. Note that the number of bits shifted is i modulo 32. For example, let HTTP.REQ.URL.LENGTH be 4. Then, HTTP.REQ.URL.LENGTH.RSHIFT(1) = HTTP.REQ.URL.LENGTH.RSHIFT(33) = 2, since 33 on division by 32 yields a remainder of 1.

`Parameters``:`

i- Right Shift Length

`Returns:` num_at

`*SIGNED16_STRING` (endian_e endianness)

Create a signed 16-bit binary string from the number.

`Parameters` (expressions not allowed) `:`

endianness- Select little or big endian

`Returns:` text_t

`*SIGNED32_STRING` (endian_e endianness)

Create a signed 32-bit binary string from the number.

`Parameters` (expressions not allowed) `:`

endianness- Select little or big endian

`Returns:` text_t

`*SIGNED8_STRING`

Create a signed 8-bit binary string from the number.

`Returns:` text_t

`*SUB` (double_at i)

Return the Double Value after subtracting the argument from the current double value.

`Parameters``:`

i- Double

`Returns:` double_at

`*SUB` (ip_address_at i)

Return the Unsigned Long Value after subtracting the argument from the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*SUB` (unsigned_long_at i)

Return the Unsigned Long Value after subtracting the argument from the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*SUB` (num_at i)

Return the Number Value after subtracting the argument from the current number value.

`Parameters``:`

i- Number

`Returns:` num_at

`*SUB` (time_local_at i)

Return the Unsigned Long Value after subtracting the argument from the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*SUB` (time_at i)

Return the Unsigned Long Value after subtracting the argument from the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*TYPECAST_DOUBLE_AT`

Typecast the Number Value to a Double value.

`Returns:` double_at

`*TYPECAST_IP_ADDRESS_AT`

Typecast the Number Value to an IP Address value.

`Returns:` ip_address_at

`*TYPECAST_TEXT_T`

Typecast the Number Value to its string representation.

`Returns:` text_t

`*TYPECAST_TIME_AT`

Typecast the Number Value to a Time value.

`Returns:` time_at

`*TYPECAST_TIME_LOCAL_AT`

Typecast the Number Value to a local time value.

`Returns:` time_local_at

`*TYPECAST_UNSIGNED_LONG_AT`

Typecast the Number Value to a Unsigned Long value.

`Returns:` unsigned_long_at

`*UNSIGNED16_STRING` (endian_e endianness)

Create an unsigned 16-bit binary string from the number.

`Parameters` (expressions not allowed) `:`

endianness- Select little or big endian

`Returns:` text_t

`*UNSIGNED32_STRING` (endian_e endianness)

Create an unsigned 32-bit binary string from the number.

`Parameters` (expressions not allowed) `:`

endianness- Select little or big endian

`Returns:` text_t

`*UNSIGNED64_STRING` (endian_e endianness)

Create an unsigned 64-bit binary string from the number.

`Parameters` (expressions not allowed) `:`

endianness- Select little or big endian

`Returns:` text_t

`*UNSIGNED8_STRING`

Create an unsigned 8-bit binary string from the number.

`Returns:` text_t

`*WEEKDAY_STRING`

Given the numeric day of the week, e.g. SYS.TIME.WEEKDAY, return the long form of the string name for that day, e.g. 0 = "Sunday", 6 = "Saturday".

`Returns:` text_t

`*WEEKDAY_STRING_SHORT`

Given the numeric day of the week, e.g. SYS.TIME.WEEKDAY, return the short form of the string name for that day, e.g. 0 = "Sun", 6 = "Sat".

`Returns:` text_t

HTTP_CACHE_CONTROL_T

This object provides for the ability to work on HTTP Cache-Control headers. The name comparison for all list operations is case insensitive.

This topic lists the expressions that are provided by this class.

`*Note` *: Expressions with the * symbol are inherited / promoted from http_header_t nvlist_at

- `IS_INVALID`

  Returns TRUE or FALSE depending on whether invalid Cache-Control headers are present. See RFC 2616 for more details.

`Returns:` bool_at

`*IS_MAX_AGE`

Returns TRUE or FALSE depending on whether the "max-age" Cache-Control header is present. See RFC 2616 for more details.

`Returns:` bool_at

`*IS_MAX_STALE`

Returns TRUE or FALSE depending on whether the "max-stale" Cache-Control header is present. See RFC 2616 for more details.

`Returns:` bool_at

`*IS_MIN_FRESH`

Returns TRUE or FALSE depending on whether the "min-fresh" Cache-Control header is present. See RFC 2616 for more details.

`Returns:` bool_at

`*IS_MUST_REVALIDATE`

Returns TRUE or FALSE depending on whether the "must-revalidate" Cache-Control header is present. See RFC 2616 for more details.

`Returns:` bool_at

`*IS_NO_CACHE`

Returns TRUE or FALSE depending on whether the "no-cache" Cache-Control header is present. See RFC 2616 for more details.

`Returns:` bool_at

`*IS_NO_STORE`

Returns TRUE or FALSE depending on whether the "no-store" Cache-Control header is present. See RFC 2616 for more details.

`Returns:` bool_at

`*IS_NO_TRANSFORM`

Returns TRUE or FALSE depending on whether the "no-transform" Cache-Control header is present. However, HTTP.REQ.CACHE_CONTROL.IS_NO_TRANSFORM will always return false since the "no-transform" cache-control header can only be present in the response. See RFC 2616 for more details.

`Returns:` bool_at

`*IS_ONLY_IF_CACHED`

Returns TRUE or FALSE depending on whether the "only-if-cached" Cache-Control header is present. See RFC 2616 for more details.

`Returns:` bool_at

`*IS_PRIVATE`

Returns TRUE or FALSE depending on whether the "private" Cache-Control header is present. See RFC 2616 for more details.

`Returns:` bool_at

`*IS_PROXY_REVALIDATE`

Returns TRUE or FALSE depending on whether the "proxy-revalidate" Cache-Control header is present. See RFC 2616 for more details.

`Returns:` bool_at

`*IS_PUBLIC`

Returns TRUE or FALSE depending on whether the "public" Cache-Control header is present. See RFC 2616 for more details.

`Returns:` bool_at

`*IS_S_MAXAGE`

Returns TRUE or FALSE depending on whether the "s-maxage" Cache-Control header is present. See RFC 2616 for more details.

`Returns:` bool_at

`*IS_UNKNOWN`

Returns TRUE or FALSE depending on whether unknown Cache-Control headers are present. See RFC 2616 for more details.

`Returns:` bool_at

`*MAX_AGE`

Returns the value of the HTTP Cache-Control header "maxage". If this header is absent or invalid, 0 is returned. See RFC 2616 for more details.

`Returns:` num_at

`*MAX_STALE`

Returns the value of the HTTP Cache-Control header "maxstale". If this header is absent or invalid, 0 is returned. See RFC 2616 for more details.

`Returns:` num_at

`*MIN_FRESH`

Returns the value of the HTTP Cache-Control header "min-fresh". If this header is absent or invalid, 0 is returned. See RFC 2616 for more details.

`Returns:` num_at

`*S_MAXAGE`

Returns the value of the HTTP Cache-Control header "s-maxage". If this header is absent or invalid, 0 is returned. See RFC 2616 for more details.

`Returns:` num_at

`*TYPECAST_HTTP_HEADER_T`

Convert http_cache_control_t to http_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_header_t : Typecast an HTTP Header object of a specific type to HTTP Header.For example: HTTP.REQ.CONTENT_LENGTH.TYPECAST_HTTP_HEADER_T)

`Returns:` http_header_t

`*AFTER_REGEX` (`re` regex)

The AFTER_REGEX operator in this object overrides the Text AFTER_REGEX operator to operate on all the instances of the current header type. Selects the Text after the text that matches the input regular expression in any instance of the header value. The order in which the header instances will be matched is from the last to the first.

For example: HTTP.REQ.HEADER("etag").AFTER_REGEX(re/KX/) will select "DAPPER" from "KXDAPPER". This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

regex- Regular Expression

`Returns:` text_t

`*AFTER_STR_ANY` (text_t patset_name)

Selects the Text that is present after the first occurrence of any of the strings that are bound to the patset named by the string argument. If there is no match to any of the strings bound to the patset in the current Text object then the result Text object has 0 length. The patset cannot have strings longer than 255 characters. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` text_t

`*AFTER_STR` (text_t s)

The AFTER_STR operator in this object overrides the Text AFTER_STR operator to operate on all the instances of the current header type. Selects Text after the first occurrence of the input string argument. The order in which the instances of the header are matched is from the last instance to the first.

HTTP/1.1 200 OK\\r\\n MyHdr: 111abc\\r\\n Content-Length: 200\\r\\n MyHdr: 111def\\r\\n \\r\\n

Examples: HTTP.RES.HEADER("MyHdr").AFTER_STR("111") selects "def" in the last instance of MyHdr, the one with value "111def". HTTP.RES.HEADER("MyHdr").AFTER_STR("1ab") selects "c" in the first instance of MyHdr, the one with value "abc111". This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*APPEND` (bool_at b)

Appends the given boolean's string representation to the current string.

`Parameters``:`

b- the boolean value to append.

`Returns:` text_t

`*APPEND` (double_at i)

Appends the given double's string representation to the current string.

`Parameters``:`

i- the double value to append.

`Returns:` text_t

`*APPEND` (ip_address_at addr)

Appends the given IPv4's string representation to the current string.

`Parameters``:`

addr- the IPv4 address to append.

`Returns:` text_t

`*APPEND` (num_at i)

Appends the given number's string representation to the current string.

`Parameters``:`

i- the number value to append.

`Returns:` text_t

`*APPEND` (time_local_at t)

Appends the given time's string representation to the current string.

`Parameters``:`

t- the time value to append.

`Returns:` text_t

`*APPEND` (time_at t)

Appends the given time's string representation to the current string.

`Parameters``:`

t- the time value to append.

`Returns:` text_t

`*APPEND` (unsigned_long_at i)

Appends the given unsigned long's string representation to the current string.

`Parameters``:`

i- the unsigned long value to append.

`Returns:` text_t

`*APPEND` (ipv6_address_at addr)

Appends the given IPv6's string representation to the current string.

`Parameters``:`

addr- the IPv6 address to append.

`Returns:` text_t

`*APPEND` (ipv6_subnet_at addr)

Appends the given IPv6 subnet's string representation to the current string.

`Parameters``:`

addr- the IPv6 subnet to append.

`Returns:` text_t

`*APPEND` (mac_address_at addr)

Appends the given MAC's string representation to the current string.

`Parameters``:`

addr- the MAC address to append.

`Returns:` text_t

`*APPEND` (text_t str)

Appends the given string to the current string.

`Parameters``:`

str- the string to append.

`Returns:` text_t

`*APPEND` (time_at t)

Appends the given time's string representation to the current string.

`Parameters``:`

t- the time value to append.

`Returns:` text_t

`*B64DECODE`

Decodes the selected text using base64 decoding.

For example, the string "TWFu" is converted to "Man"

`Returns:` text_t

`*B64ENCODE`

Encodes the selected text using base64 encoding.

For example, the string "Man" is converted to "TWFu"

`Returns:` text_t

`*BEFORE_REGEX` (`re` regex)

The BEFORE_REGEX operator in this object overrides the Text BEFORE_REGEX operator to operate on all the instances of the current header type. Selects the Text before the text that matches the input regular expression in any instance of the header value. The order in which the header instances will be matched is from the last to the first.

For example: HTTP.RES.HEADER("content-type").BEFORE_REGEX(re#/#) will select "text" from "text/plain". This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

regex- Regular Expression

`Returns:` text_t

`*BEFORE_STR_ANY` (text_t patset_name)

Selects the Text that is present before the first occurrence of any of the strings that are bound to the patset or datasetnamed by the string argument. If there is no match to any of the strings bound to the patset in the current Text object then the result Text object has 0 length. The patset cannot have strings longer than 255 characters. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` text_t

`*BEFORE_STR` (text_t s)

The BEFORE_STR operator in this object overrides the Text BEFORE_STR operator to operate on all the instances of the current header type. Selects Text before the first occurrence of the input string argument. The order in which the instances of the header are matched is from the last instance to the first.

HTTP/1.1 200 OK\\r\\n MyHdr: abc111\\r\\n Content-Length: 200\\r\\n MyHdr: def111\\r\\n \\r\\n

Examples: HTTP.RES.HEADER("MyHdr").BEFORE_STR("111") selects "def" in the last instance of MyHdr, the one with value "def111". HTTP.RES.HEADER("MyHdr").BEFORE_STR("bc1") selects "a" in the first instance of MyHdr, the one with value "abc111". This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*BETWEEN` (text_t start, text_t end)

Results in Boolean TRUE value if length of the Text object is greater than or equal to the sum of the Start and End argument lengths and if the prefix of the Text object matches the Start string argument and if the Suffix of the Text object matches the End string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

start- Start

end- End

`Returns:` bool_at

`*BIN_DECODE` (binary_encoding_e encoding)

Decode the encoded input into its original byte sequence. An incorrectly enooded input will result in an Undef error.

`Parameters` (expressions not allowed) `:`

encoding- specifies how the bytes are encoded.

`Returns:` text_t

`*BIN_ENCODE` (binary_encoding_e encoding)

Encode the input byte sequence. Note that BIN_ENCODE(hex_colons) is equivalent to BLOB_TO_HEX().

`Parameters` (expressions not allowed) `:`

encoding- specifies how the bytes are to be encoded.

`Returns:` text_t

`*BLOB_TO_HEX`

Convert to hexadecimal representation and select text.

For example, the byte string abc is converted to 61:62:63.

`Returns:` text_t

`*COMPARE` (text_t s)

Results in a Number Value which is the result of comparison of the input argument with the Text object. The result is greater than 0 if the Text object is lexicographically greater than the argument. The result is 0 if the Text object and the argument match. The result is less than 0 if the Text object is lexicographically lesser than the argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` num_at

`*CONTAINS_ANY` (text_t patclass_name)

The CONTAINS_ANY in this object overrides the Text CONTAINS_ANY operator to operate on all the instances of the current header type. Returns Boolean TRUE if any of the patterns associated with input patclass is present in any instance of the header value. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patclass_name- Patclass Name

`Returns:` bool_at

`*CONTAINS_INDEX` (text_t patclass_name)

The CONTAINS_INDEX in this object overrides the Text CONTAINS_INDEX operator to operate on all the instances of the current header type. Returns the index of the matching pattern associated with input patclass that is present in any instance of the header value. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed)`:`

patclass_name- Patclass Name

`Returns:` num_at

`*CONTAINS` (text_t s)

The CONTAINS in this object overrides the Text CONTAINS operator to operate on all the instances of the current header type. Returns Boolean TRUE if the input Pattern String is present in any instance of the header value.

GET / HTTP/1.1\\r\\n Host: abc.com\\r\\n MyHdr: abc\\r\\n Content-Length: 200\\r\\n MyHdr: def\\r\\n

HTTP/1.1 200 OK\\r\\n MyHdr: abc\\r\\n Content-Length: 200\\r\\n MyHdr: def\\r\\n \\r\\n

Examples: HTTP.RES.HEADER("MyHdr").CONTAINS("de") is TRUE.
HTTP.RES.HEADER("MyHdr").CONTAINS("bcd") is FALSE.
HTTP.REQ.HEADER("MyHdr").CONTAINS("de") is TRUE.
HTTP.REQ.HEADER("MyHdr").CONTAINS("bcd") is FALSE. The system does not concatenate the different values. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- Pattern String

`Returns:` bool_at

`*COUNT`

Return a Number Value giving the number of name-value components in the list. If the last Name-Value List component is of zero length or is all spaces then it is ignored.

`Returns:` num_at

`*CRC32`

Returns a 32-bit integer computed by applying a CRC (cyclic redundancy check) function to the selected text. This is the CRC function used by Ethernet, MPEG-2, PKZIP, GZIP, PNG, and many other applications. For example, the expression to compute the CRC value of the (first 1000 bytes of the) body of an HTTP request is: HTTP.REQ.BODY(1000).CRC32

`Returns:` num_at

`*DECODE_USING_TEXT_MODE`

Decodes the selected text using the currently configured text encoding methods like URLENCODED, BACKSLASH_ENCODED, PLUS_AS_SPACE, NOURLENCODED, NO_BACKSLASH_ENCODED and NO_PLUS_AS_SPACE. Text encoding methods are set using SET_TEXT_MODE method.

`Returns:` text_t

`*DECRYPT`

Decrypt the selected base64-encoded ciphertext using the configured encryptionParams.

`Returns:` text_t

`*DECRYPT` (binary_encoding_e in_encoding)

Decrypt the selected ciphertext using the configured encryptionParams.

`Parameters` (expressions not allowed) `:`

in_encoding- specifies how the input ciphertext is encoded. If the ciphertext is not encoded as specified, causes an Undef error.

`Returns:` text_t

`*DECRYPT` (text_t encryptionKey)

Decrypt the selected base64-encoded encrypted bytes using the configured encryption key.

`Parameters` (expressions not allowed) `:`

encryptionKey- identifies the encryptionKey object to provide the cipher method, mode, padding, key, encrypted format and optional initialization vector (IV).

`Returns:` text_t

`*DECRYPT` (text_t encryptionKey, binary_encoding_e in_encoding)

Decrypt the selected base64-encoded encrypted bytes using the configured encryption key.

`Parameters` (expressions not allowed) `:`

encryptionKey- identifies the encryptionKey object to provide the cipher method, mode, padding, key, encrypted format, and optional initialization vector (IV).

in_encoding- specifies how the input ciphertext is encoded. If the ciphertext is not encoded as specified, causes an Undef error.

`Returns:` text_t

`*DIGEST` (digest_method_e method)

Returns a byte sequence computed by applying the the specified message digest method to the selected text.

`Parameters` (expressions not allowed) `:`

method- digest method to apply to the input text

`Returns:` text_t

`*ENCRYPT`

Encrypt the selected plaintext bytes using the configured encryptionParams. The resulting ciphertext is base64-encoded.

`Returns:` text_t

`*ENCRYPT` (binary_encoding_e out_encoding)

Encrypt the selected plaintext bytes using the configured encryptionParams.

`Parameters` (expressions not allowed) `:`

out_encoding- specifies how the resulting ciphertext is encoded.

`Returns:` text_t

`*ENCRYPT` (text_t encryptionKey)

Encrypt the selected cleartext bytes using the configured encryption key.

`Parameters` (expressions not allowed) `:`

encryptionKey- identifies the encryptionKey object to provide the cipher method, mode, padding, key, encrypted format and optional initialization vector (IV).

`Returns:` text_t

`*ENCRYPT` (text_t encryptionKey, binary_encoding_e out_encoding)

Encrypt the selected cleartext bytes using the configured encryption key.

`Parameters` (expressions not allowed) `:`

encryptionKey- identifies the encryptionKey object to provide the cipher method, mode, padding, key, encrypted format and optional initialization vector (IV).

out_encoding- specifies how the resulting ciphertext is encoded.

`Returns:` text_t

`*ENDSWITH_ANY` (text_t patset_name)

Results in Boolean TRUE value if the Text ends with any of the strings that are bound to the patset or dataset named by the string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` bool_at

`*ENDSWITH_INDEX` (text_t patset_name)

Returns the numerical index of the matching string, if the Text ends with any of the strings that are bound to the patset or dataset named by the string argument. Returns 0 if there is no match. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` num_at

`*ENDSWITH` (text_t end)

Results in Boolean TRUE value if a suffix of the Text object matches the string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

end- String

`Returns:` bool_at

`*EQUALS_ANY` (text_t patset_name)

The EQUALS_ANY in this object overrides the Text EQUALS_ANY operator to operate on all the instances of the current header type. Returns Boolean TRUE if any of the patterns associated with input patset is equal to any instance of the header value. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed)`:`

patset_name- Patset Name

`Returns:` bool_at

`*EQUALS_INDEX` (text_t patset_name)

The EQUALS_INDEX in this object overrides the Text EQUALS_INDEX operator to operate on all the instances of the current header type. Returns the index of the matching pattern associated with input patset is equal to any instance of the header value. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed)`:`

patset_name- Patset Name

`Returns:` num_at

`*EQ` (text_t s)

Results in Boolean TRUE value if the Text object matches the input argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*EXISTS`

Returns TRUE if an instance of the current header type exists.

`Returns:` bool_at

`*GET_SIGNED16` (`uint` n, endian_e endianness)

Get the 16-bit signed binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

endianness- Select little or big endian

`Returns:` num_at

`*GET_SIGNED32` (`uint` n, endian_e endianness)

Get the 32-bit signed binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

endianness- Select little or big endian

`Returns:` num_at

`*GET_SIGNED8` (`uint` n)

Get the 8-bit signed binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

`Returns:` num_at

`*GET_UNSIGNED16` (`uint` n, endian_e endianness)

Get the 16-bit unsigned binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

endianness- Select little or big endian

`Returns:` num_at

`*GET_UNSIGNED32` (`uint` n, endian_e endianness)

Get the 32-bit unsigned binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

endianness- Select little or big endian

`Returns:` unsigned_long_at

`*GET_UNSIGNED64` (`uint` n, endian_e endianness)

Get the 64-bit unsigned binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

endianness- Select little or big endian

`Returns:` unsigned_long_at

`*GET_UNSIGNED8` (`uint` n)

Get the 8-bit unsigned binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

`Returns:` num_at

`*GET_URLSET_METADATA` (text_t urlset_name)

Returns metadata value corresponding to pattern in the urlset. The matching is case-insensitive for domains, but case-sensitive for paths. If no pattern is matched within the urlset, the return value is a NULL string. For example:

- HTTP.REQ.HOST.APPEND(HTTP.REQ.URL).GET_URLSET_METADATA("urlset_forbidden") returns value when the combined domain and URL is looked up in the urlset whose name is "urlset_forbidden".

`Parameters` (expressions not allowed) `:`

urlset_name- urlset name

`Returns:` text_t

`*GE` (text_t s)

Results in Boolean TRUE value if the Text object is greater than or equal to the input argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*GRPC`

Interprets a text_t string as a Protocol Buffer (protocol_buffer_t type). Example: HTTP.REQ.BODY(1000).GRPC.STRING(1).EQ("bookname")

`Returns:` protocol_buffer_t

`*GT` (text_t s)

Results in Boolean TRUE value if the Text object is greater than the input argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*HASH`

Returns a positive 31 bit integer value computed by applying a proprietary NetScaler hash function to the selected text. This function is not case- sensitive and ignores whitespaces. For example, applying the HASH function to two strings "Ab c" and "abc" would produce the same value. This

function should not be used for security purposes; use instead the DIGEST function with one of the standard digest methods.

`Returns:` num_at

`*HMAC` (text_t hmacKey)

Returns a byte sequence computed by applying the HMAC (Hash Message Authenticastion Code) function to the selected text using the configured HMAC key.

`Parameters` (expressions not allowed) `:`

hmacKey- indentifies the hmacKey object to provide the digest (hash) method and the key.

`Returns:` text_t

`*HMAC` (text_t hmacKey, binary_encoding_e out_encoding)

Returns a byte sequence computed by applying the HMAC (Hash Message Authenticastion Code) function to the selected text using the configured HMAC key .

`Parameters` (expressions not allowed) `:`

hmacKey- indentifies the hmacKey object to provide the digest (hash) method and the key.

out_encoding- specifies how the resulting HMAC is encoded.

`Returns:` text_t

`*HTML_XML_SAFE`

Apply XML safe transform and select text.

Converts '<', '>' and '&' in the input text to '<', '>' and '&' respectively; other characters in the input are not modified. This transform safeguards against XSS based attacks. This is a read only operation.

`Returns:` text_t

`*HTTP_HEADER_SAFE`

Apply Header safe transform and select text. Converts all new line ('\\n') characters present in the input text to '%0A' so that they can safely be used in HTTP headers. This transform safeguards against response-splitting attacks. This is a read only operation.

`Returns:` text_t

`*HTTP_URL_SAFE`

Apply URL safe transform and select text. Converts URL unsafe characters to corresponding '%xx' values and retains the rest. This is a read only operation.

```
Based on RFC2396, following are considered URL safe characters:

    Alpha-numeric characters: a-z, A-Z, 0-9

    Hyphen and underscore: "-", "_"

    Dot: "."

    Exclamation mark: "!"

    Tilde: "~"

    Asterix: "&ast;"

    Single quote: "'"

    Open and close parentheses: "(", ")"

    Semi-colon: ";"

    Colon: ":"

    At symbol: "@"

    Question mark: "?"

    Equals: "="

    Dollar: "$"

    Percent: "%"

    Ampersand: "&"

    Plus: "+"
```

```
Comma: ","

Forward slash: ".html"
```

The rest are converted to %XX encoding, 'XX' is the hex-based representation of the input character. If the requirement is to encode all but URL unreserved characters, please consider using URL_RESERVED_CHARS_SAFE method.

`Returns:` text_t

`*INSTANCE` (`uint` lineno)

An HTTP header can have multiple occurrences. INSTANCE(0) will select the last header line of the current type, INSTANCE(1) will select the last but one header line and so on. The counting goes backward. Only the last 15 instances of a header are accessible. Therefore Instance Number cannot be greater than 14.

HTTP/1.1 200 OK\\r\\n MyHdr: abc\\r\\n Content-Length: 200\\r\\n MyHdr: def\\r\\n \\r\\n

For example: HTTP.RES.HEADER("MyHdr").INSTANCE(1) will return a Text object referring to "MyHdr: abc\\r\\n". It can not be used in HTTP response processing contexts.

`Parameters` (expressions not allowed) `:`

lineno- Instance Number

`Returns:` text_t

`*IS_BOOL_AT`

Results in Boolean TRUE value if the Text is of boolean type.

`Returns:` bool_at

`*IS_DOUBLE_AT`

Results in Boolean TRUE value if the Text is of double data type.

`Returns:` bool_at

`*IS_IPV6_AT`

Results in Boolean TRUE value if the Text is of IPv6 data type.

`Returns:` bool_at

`*IS_IPV6_SUBNET_AT`

Results in Boolean TRUE value if the Text is of IPv6 subnet data type.

`Returns:` bool_at

`*IS_IP_AT`

Results in Boolean TRUE value if the Text is of IPv4 data type.

`Returns:` bool_at

`*IS_MAC_ADDRESS_AT`

Results in Boolean TRUE value if the Text is of mac address data type.

`Returns:` bool_at

`*IS_NUM_AT`

Results in Boolean TRUE value if the Text is of number type.

`Returns:` bool_at

`*IS_NUM_AT` (num_format_e format)

Results in Boolean TRUE value if the Text is of number type with given input base.

`Parameters` (expressions not allowed) `:`

format- number format

`Returns:` bool_at

`*IS_STRINGMAP_KEY` (text_t string_map_name)

Returns true if the string that it operates on is present in the string map. Text mode IGNORECASE, NOIGNORECASE - controls whether key lookup in string map is case sensitive or not. For example:

- HTTP.REQ.URL.IS_STRINGMAP_KEY("url_stringmap") returns true if value of HTTP.REQ.URL is present as key in the string map whose name is "url_stringmap".

- HTTP.REQ.URL.SET_TEXT_MODE(IGNORECASE). IS_STRINGMAP_KEY("url_stringmap") returns true if value of HTTP.REQ.URL is present as key in the string map whose name is "url_stringmap". Key lookup in this case is done case-insensitively.

`Parameters` (expressions not allowed) `:`

string_map_name- identifies the string map.

`Returns:` bool_at

`*IS_TIME_AT`

Results in Boolean TRUE if the Text follows any of the standard time formats given below, otherwise false. Tue, 05 Nov 1994 08:12:31 GMT RFC822 Tuesday, 05-Nov-94 08:12:31 GMT RFC850 Tue Nov 4 08:12:31 1994 asctime

`Returns:` bool_at

`*IS_UNSIGNED_LONG_AT`

Results in Boolean TRUE value if the Text is of unsigned long data type.

`Returns:` bool_at

`*IS_UNSIGNED_LONG_AT` (num_format_e format)

Results in Boolean TRUE value if the Text is of unsigned long data type with given input base.

`Parameters` (expressions not allowed) `:`

format- number format

`Returns:` bool_at

`*JWT_VERIFY_CERTKEY` (text_t certkey_name)

Verifies the signature on the input JSON Web Token (JWT), using the RSA public key in the X.509 certificate in the specified certkey object. The token has the format HEADER.PAYLOAD.SIGNATURE where

- HEADER is a base64-encoded JSON structure indicating a signature algorithm and token type, e.g.'{"alg":"RS256","typ":"JWT"}'
- PAYLOAD is a base64-encoded JSON structure with asserted claims, e.g. '{"loggedInAs":"admin","iat":1422779638}'

- SIGNATURE is the base64-encoded bytes for the signature on HEADER.PAYLOAD.

Returns true if the signature is verified for the header and payload using the specified public key; false if the signature is not verified

`Parameters``:`

certkey_name- identifies the certkey object containing an X.509 certificate holding the RSA public key. Results in an Undef error if the certkey object does not exist or does not contain an X.509 certificate with an RSA public key, if the token is not correctly formatted, or if the verification operation cannot complete.

`Returns:` bool_at

`*JWT_VERIFY_XML` (text_t xml_pkey)

Verifies the signature on the input JSON Web Token (JWT), using the RSA public key supplied by the specified XML element. The token has the format HEADER.PAYLOAD.SIGNATURE where

- HEADER is a base64-encoded JSON structure indicating a signature algorithm and token type, e.g.'{"alg":"RS256","typ":"JWT"}'
- PAYLOAD is a base64-encoded JSON structure with asserted claims, e.g. '{"loggedInAs":"admin","iat":1422779638}'
- SIGNATURE is the base64-encoded bytes for the signature on HEADER.PAYLOAD.

Returns true if the signature is verified for the header and payload using the specified public key; false if the signature is not verified

`Parameters``:`

xml_pkey- an expression that supplies an <RSAKeyValue> element with the public key. Results in an Undef error if the XML element is invalid or does not correctly specify an RSA public key, if the token is not correctly formatted, or if the verification operation cannot complete.

`Returns:` bool_at

`*LENGTH`

Results in a Number Value that is the number of characters (not bytes) in the Text object.

`Returns:` num_at

`*LE` (text_t s)

Results in Boolean TRUE value if the Text object is less than or equal to the input argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*LOCATION_LONG`

Get the location qualifier from CLIENT.IP.SRC.LOCATION.GET(n) (ISO short name) and then convert it to human readable long name. This conversion is valid only for country names. Correct Country qualifier value (number) in GET(n) is left up to the user as qualifiers are user configurable. Expression example: CLIENT.IP.SRC.LOCATION.GET(1).LOCATION_LONG For example: Data from each expression CLIENT.IP.SRC.LOCATION: NA.US.California.SantaClara.*.* CLIENT.IP.SRC.LOCATION.GET(1): US CLIENT.IP.SRC.LOCATION.GET(1).LOCATION_LONG: United States

`Returns:` text_t

`*LT` (text_t s)

Results in Boolean TRUE value if the Text object is less than the input argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*MAP_STRING_DEFAULT_TO_KEY` (text_t string_map_name)

Returns the value corresponding to the key in the string map. This is similar to the MAP_STRING method, but if the key is not present then instead of returning a null string, it returns the key itself. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed)`:`

string_map_name- identifies the string map.

`Returns:` text_t

`*MAP_STRING` (text_t string_map_name)

Returns value corresponding to key in the string map. Key is the string that it is given as input. Text mode IGNORECASE, NOIGNORECASE - controls whether key lookup in string map is case sensitive or not. For example:

- HTTP.REQ.URL.MAP_STRING("url_stringmap") returns value when the value of HTTP.REQ.URL is used as key in the string map whose name is "url_stringmap".
- HTTP.REQ.URL.SET_TEXT_MODE(IGNORECASE). MAP_STRING("url_stringmap") returns value when the value of HTTP.REQ.URL is used as key in the string map whose name is "url_stringmap". Key lookup in this case is done case-insensitively.

`Parameters` (expressions not allowed) `:`

string_map_name- identifies the string map.

`Returns:` text_t

`*MARK_SAFE`

Mark the PIXL expression safe without applying any safe transform.

`Returns:` text_t

`*MAX` (text_t s)

Compares the string argument with the current string and returns the max string. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*MIN` (text_t s)

Compares the string argument with the current string and returns the min string. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*NAMES`

Extracts a list of only the names from the name-value pair list. For example the list 'a=b,c="d=e,f",g=h' will result in the list 'a,c,g'. Empty elements will be ignored.

`Returns:` list_t

`*NAME` (`uint` i)

Operate as Text on the name component of the specified name-value component in the list. The index of the name-value component given by the argument is 0-based. If the specified index is greater than the number of components then a zero length Text object is produced.

`Parameters` (expressions not allowed) `:`

i- Index

`Returns:` text_t

`*NAME_VALUE` (`uint` i)

Returns the element in the list identified by the parameter. The parameter is a 0-based index in to the list. The result is a string. If the specified index is greater than the number of components then a zero length string is produced.

`Parameters` (expressions not allowed) `:`

i- Index

`Returns:` text_t

`*NAME_VALUE` (text_t name)

Operate as Text on the name-value component in the list. The name-value component is specified by the argument by providing the name whose name-value is needed. The first component that matches the name is selected. The matching process honors the IGNORECASE and the NOIGNORECASE text modes. The URLENCODED and the NOURLENCODED text modes are ignored.

`Parameters` (expressions not allowed) `:`

name- Name

`Returns:` text_t

`*NAME_VALUE` (text_t name, `uint` i)

Operate as Text on the name-value component in the list. The name-value component is specified by the argument by providing the name whose name-value is needed. In a name-value list the same name can be repeated multiple times. The Index argument controls which occurence of the matching name-value component should be selected. The Index is 0-based. If the Index is too big then the Text object that is produced will have zero length. The matching process honors the IGNORECASE and the NOIGNORECASE text modes. The URLENCODED and the NOURLENCODED text modes are ignored.

`Parameters` (expressions not allowed) `:`

name- Name

i- Index

`Returns:` text_t

`*NE` (text_t s)

Results in Boolean TRUE value if the Text object is not equal to the input argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*NORMALIZE_URL`

Normalize URL. Normalizes a URL by doing "percent" decoding. See the description for URLENCODED in the SET_TEXT_MODE function. This performs the equivalent of SET_TEXT_MODE(URLENCODED).DECODE_USING_TEXT_MODE, except that it does not change the value of the current text mode.

`Returns:` text_t

`*PKEY_ENCRYPT_PEM_NO_PADDING` (text_t pem_pkey)

Encrypts the input text using the RSA public key provided by the PEM string and RSA_NO_PADDING padding method. The input text to be encrypted cannot be longer than the public key length minus 11 bytes for padding. For example, for a 1024-bit (128 byte) key, the input text cannot be longer than 128 - 11 = 117 bytes. An Undef error will occur if the input text is too

long. A null input will also cause an Undef error. Returns the (unencoded binary) encrypted text, which is typically base-64 encoded for use in a message.

`Parameters``:`

pem_pkey- a text expression that supplies a RSA public key in the PEM format. If the text value is not a valid PEM RSA PUBLIC KEY encoding, an Undef error will occur. Example (a 1024-bit public key):

```
"-----BEGIN RSA PUBLIC KEY-----" +

"MIGJAoGBAKl5vgQEj73Kxp+9yn1v5gPR1pnc4oLM2a0kaWwBOsB6rzCIy6znwnvw" +

"CY1xRvQhRlJSAyJbloL7wZFIJ2FOR8Cz+8ZQWXU2syG+udi4EnWqLgFYowF9zK+o" +

"79az597eNPAjsHZ/C2oL/+6qY5a/f1z8bQPrHC4GpFfAEJhh/+NnAgMBAAE=" +

"-----END RSA PUBLIC KEY-----"
```

`Returns:` text_t

`*PKEY_ENCRYPT_PEM` (text_t pem_pkey)

Encrypts the input text using the RSA public key provided by the PEM string and the RSA_PKCS1_PADDING padding method. The input text to be encrypted cannot be longer than the public key length minus 11 bytes for padding. For example, for a 1024-bit (128 byte) key, the input text cannot be longer than 128 - 11 = 117 bytes. An Undef error will occur if the input text is too long. A null input will also cause an Undef error. Returns the (unencoded binary) encrypted text, which is typically base-64 encoded for use in a message.

`Parameters``:`

pem_pkey- a text expression that supplies a RSA public key in the PEM format. If the text value is not a valid PEM RSA PUBLIC KEY encoding, an Undef error will occur. Example (a 1024-bit public key):

```
"-----BEGIN RSA PUBLIC KEY-----" +

"MIGJAoGBAKl5vgQEj73Kxp+9yn1v5gPR1pnc4oLM2a0kaWwBOsB6rzCIy6znwnvw" +

"CY1xRvQhRlJSAyJbloL7wZFIJ2FOR8Cz+8ZQWXU2syG+udi4EnWqLgFYowF9zK+o" +
```

```
"79az597eNPAjsHZ/C2oL/+6qY5a/f1z8bQPrHC4GpFfAEJhh/+NnAgMBAAE=" +

"-----END RSA PUBLIC KEY-----"
```

`Returns:` text_t

`*PKEY_SIGN_CERTKEY` (text_t certkey_name)

Generates a binary digital signature using the SHA-256 message digest function and an RSA private key from the specified SSL certKey object.

`Parameters``:`

certkey_name- identifies the configured certKey object. Results in an Undef error if the certkey object does not exist or does not contain an RSA private key, or if the signing operation cannot complete.

`Returns:` text_t

`*PKEY_SIGN_XML` (text_t xml_pkey)

Generates a binary digital signature using the SHA-256 message digest function and an RSA private key from the specified XML element.

`Parameters``:`

xml_pkey- an expression that supplies an <RSAKeyValue> element with the private key. Example: <RSAKeyValue> <Modulus>qXm+BASPvcrGn73KfW/
mA9HWmdzigszZrSRpbAE6wHqvMIjLrOfCe/
AJjXFG9CFGUlIDIluWgvvBkUgnYU5HwLP7xlBZdTazIb652LgSdaouAVijAX3Mr6jv1rPn3t408COwdn8Lagv/
7qpjlr9/XPxtA+scLgakV8AQmGH/42c=</Modulus> <Exponent>AQAB</Exponent>"zNjysxcIJV/
J9cTpIgPp2/x1IXHT5GTH8OMuNad0qtRSLjU1QYUmmkm9QcJJAN+7h8FEXWGabySUzBrHj/
IEbw==" <DP>QavUDQLLQpnPJXtVAo6CYhxOMCd68mwTxYKKNLjmC0pd54SFHllTLPE1FZU5EjK6q3nCeijonpfH+XX
DP> <DQ>EiXOKouJzzXTQJC3TqomF7Uf81yQNxWumOqnd11kepXgyfMwyqMvLlAGEkNSEF/
Bz18R3Wv+MIZ/IC3nLBt2xQ==</DQ>
<InverseQ>ocuCmz36CP+N2aGqxaU+BKD5+3RLgRq9LFhULEz2jKx0iV9r76jsAxn3sLcTYYO9eqRPy2cz74A
nw==</InverseQ> <D>fTBD773a3GzcmgVdfZlaBLpN1ux2mf5uUVrTUQf7eVFm9egm4/
tzC5A9zjC+I/oscwTH8epL3UfRLdtp05Q6pWfJBXEnGo0QmOFFBK4pLx/
5JJpPGZ69ovDFEVOUHyiCfKE/g97T4WX3us0nFe1272zwGlHarM1YYwvfeE08UdE=</D> </

RSAKeyValue> Results in an Undef error if the XML element is invalid or does not correctly specify an RSA private key, or if the signing operation cannot complete.

`Returns:` text_t

`*PKEY_VERIFY_CERTKEY` (text_t certkey_name, text_t signature)

Verifies if the input text matches the specified signature generated using the SHA-256 messge digest function and the RSA private key associated with the specified RSA public key in the X.509 certificate in the specified certKey object. Returns true if the signature is verified, false otherwise.

`Parameters``:`

certkey_name- identifies the certkey object containing an X.509 certificate holding the RSA public key.

signature- the binary signature. Results in an Undef error if the certkey object does not exist or does not contain an X.509 certificate with an RSA public key, or if the verification operation cannot complete.

`Returns:` bool_at

`*PKEY_VERIFY_XML` (text_t xml_pkey, text_t signature)

Verifies if the input text matches the specified signature generated using the SHA-256 messge digest function and the RSA private key associated with the RSA public key supplied by the specified XML element. Returns true if the signature is verified, false otherwise.

`Parameters``:`

xml_pkey- an expression that supplies an <RSAKeyVAlue> element with the public key. Example: <RSAKeyValue> <Modulus>qXm+BASPvcrGn73KfW/mA9HWmdzigszZrSRpbAE6wHqvMIjLrOfCe/AJjXFG9CFGUlIDIluWgvvBkUgnYU5HwLP7xlBZdTazIb652LgSdaouAVijAX3Mr6jv1rPn3t408COwdn8Lagv/7qpjlr9/XPxtA+scLgakV8AQmGH/42c=</Modulus> <Exponent>AQAB</Exponent> </RSAKeyValue>

signature- the binary signature. Results in an Undef error if the XML element is invalid or does not correctly specify an RSA public key, or if the verification operation cannot complete.

`Returns:` bool_at

`*PREFIX` (`char` c, `uint` i)

Select a prefix of the Text. The selected prefix is the longest prefix that has at most Count (2nd argument) occurrences of character in the 1st argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

c- Character

i- Count

`Returns:` text_t

`*PREFIX` (`uint` i)

Select a prefix of the Text. The length of the prefix is equal to the number in the argument. If there aren't enough characters in the Text object then the entire Text is selected.

`Parameters``:`

i- Prefix Length

`Returns:` text_t

`*REGEX_MATCH` (`re` regex)

The REGEX_MATCH operator in this object overrides the Text REGEX_MATCH operator to operate on all the instances of the current header type. Returns Boolean TRUE if the input regular expression matches any instance of the header value. The order in which the header instances will be matched is from the last to the first.

The regular expression has to be of the format: `re<delimiter>regular expression<same delimiter>`

The regular expression cannot be bigger than 1499 characters.

The regular expression should be acceptable by the PCRE regular expression library. Look at http://www.pcre.org/pcre.txt for documentation on the regular expression syntax. In particular, look at the pcrepattern man page.

There are some differences in the allowed syntax w.r.t PCRE syntax. Backreferences are not allowed. It is recommended to not use recursive regular expressions. The dot metacharacter matches newlines also. Unicode is not supported. SET_TEXT_MODE(IGNORECASE) overrides the (?i) internal option specified in the regular expression.

The PCRE library configuration can be seen in the system log, after executing 'nsapimgr -B" call ns_pixl_regex_show_config()"' at the shell prompt.

Some examples:

- HTTP.REQ.HOSTNAME.REGEX_MATCH(re/\[\[:alpha:\]\]+(abc){2,3}/)
- HTTP.REQ.URL.SET_TEXT_MODE(URLENCODED).REGEX_MATCH(re#(a*b+c*)#)
- HTTP.REQ.URL.REGEX_MATCH(re/a(?i)b/) matches ab and aB
- HTTP.REQ.URL.SET_TEXT_MODE(IGNORECASE).REGEX_MATCH(re/ab/) matches ab, aB, Ab and AB
- HTTP.REQ.BODY.REGEX_MATCH(re/(?ixm) (\^ab (.*) cd$) /) does a case-insensitive, multiline match where the dot metacharacter matches newline also. The regex itself can contain whitespace which will be ignored during the matching (x - extended regex).

This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

regex- Regular Expression

`Returns:` bool_at

`*REGEX_REPLACE` (`re` regex, text_t replacement, replacemode_e mode)

Selects the text that matches the given regular expression argument and replaces it with the the text given in the second argument. The third argument specifies whether the first match is only replaced when multiple matches occur in the text or all matches are replaced. The match may occur anywhere within the text - if you wish to "anchor" this, use "\^" at the start of the regex and/or "$" at the end of the regex. When the regular expression does not match the given string then the same string is returned.

For example: HTTP.RES.BODY(999).REGEX_REPLACE(re!\\bpassword:\\s*\\b!, "password: ***", ALL) will replace all occurrences of "password:" with "password: ***" This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

regex- Regular Expression

replacement- String to replace the match

mode- Mode of replacement

`Returns:` text_t

`*REGEX_SELECT` (`re` regex)

The REGEX_SELECT operator in this object overrides the Text REGEX_SELECT operator to operate on all the instances of the current header type. Selects the Text that matches the input regular expression in any instance of the header value. The order in which the header instances will be matched is from the last to the first.

For example: HTTP.REQ.HEADER("via").REGEX_SELECT(re!NS-CACHE-\\d\\.\\d:\\s*\\d{1,3}!) will select "NS-CACHE-7.0: 70" This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

regex- Regular Expression

`Returns:` text_t

`*REPEAT` (`uint` i)

Produces a string which contains 'i' sequential copies of the input string.

`Parameters``:`

i- the number of times to repeat the string (0 or more)

`Returns:` text_t

`*REPLACE_ALL_VALUES` (text_t value)

Replaces all the values in each name-value pair with the specified string argument. For example, given argument string "?" the list 'a=b,c=d,e=f' will result in the name-value list 'a=?,c=?,e=?'. Quotes will be stripped from the values being replaced. Empty values will be replaced with the value provided. Empty elements will be preserved.

`Parameters` (expressions not allowed) `:`

value- value to replace existing values

`Returns:` nvlist_t

`*SET_CHAR_SET` (charset_e charset)

Set the character set to use for subsequent functions that use text.

`Parameters` (expressions not allowed) `:`

charset- Character Set

`Returns:` http_cache_control_t

`*SET_TEXT_MODE` (textmode_e mode)

The mode setting of a Text object controls the behavior of many Text operations. The Text mode settings may also control the behavior of some operations in objects (like List) that build upon the Text object. IGNORECASE, NOIGNORECASE - controls whether string comparison is case sensitive or not. URLENCODED - If set then all Text operations are carried out after translating all %HH or %uHHHH encodings in the underlying byte stream. 1. %HH will be translated to the character Y where HH denotes the ascii value of character Y in hexadecimal. For example, the encoded text "http%3a/.html" will be decoded to "http:/.html" 2. %uWWHH will be translated to the character sequence YZ where WW denotes the ascii value of character Y in hexadecimal and HH denotes the ascii value of character Z in hexadecimal. For example, the encoded text "http%u3a2f.html" and "http%u003a/.html" will both be decoded to"http:/.html" NOURLENCODED - Indicates that no percent encodings are present in the Text object. No percent decoding will be performed on the Text object. PLUS_AS_SPACE - If set then all Text operations are carried out after converting occurrences of the plus character to whitespace. For example, the text "hello+world" will be decoded to "hello world" NO_PLUS_AS_SPACE - If set, then the plus character will not be converted to whitespace in the Text object. BACKSLASH_ENCODED - If set, then all Text operations are carried out after performing the following operations: 1. \\XXX will be translated to the character Y where XXX denotes the ascii value of character Y in octal. The valid range of octal values for this type of encoding is \\0 to \\377. For example, the encoded text "http\\72/.html" and "http\\072/.html" will both be decoded to "http:/.html" 2. \\xHH will be translated to the character Y where HH denotes the ascii value of character Y in hexadecimal. For example, the encoded text "http\\x3a/.html" will be decoded to "http:/.html" 3. \\\\uWWXX will be translated to the character sequence YZ where WW denotes the ascii value of character Y in hexadecimal and XX denotes the ascii value of character Z in hexadecimal. For example, the encoded text "http%u3a2f.html" and "http%u003a/.html" will both be decoded to"http:/.html" 4. Occurences of "\\b", "\\n", "\\t", "\\f" and "\\r" are translated to the corresponding ascii characters. NO_BACKSLASH_ENCODED - If set, then backslash decoding will not be performed on the Text object. BAD_ENCODE_RAISE_UNDEF - If set, then UNDEF is raised if either the URLENCODED or BACKSLASH_ENCODED mode is set and a bad encoding corresponding to the specified encoding mode is encountered. NO_BAD_ENCODE_RAISE_UNDEF - If set, then UNDEF will not be raised when a bad encoding is encountered in the Text object. The Text operations operate on characters (as opposed to operating on bytes). By default a single byte represents a character

using the ASCII encoding. But if URLENCODED mode is set then 3 bytes may represent a character. A PREFIX(3) operation will select the first 3 characters in the Text object. That means it may select up to 9 bytes for URLENCODED Text object. In the case of multibyte decodings as a result of %uXXXX or \\\\uXXXX, Text operations which attempt to treat the multiple decoded bytes as distinct characters are not allowed.

`Parameters` (expressions not allowed) `:`

mode- Text Mode

`Returns:` http_cache_control_t

`*SKIP` (`char` c, `uint` i)

Select the Text after skipping over a prefix of the current Text. The skipped over prefix is the longest prefix that has at most Count (2nd argument) occurrences of character in the 1st argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

c- Character

i- Count

`Returns:` text_t

`*SKIP` (`uint` i)

Select the Text after skipping over a prefix in the current Text. The length of the prefix is equal to the number in the argument. If there aren't enough characters in the Text object then the entire Text is skipped over.

`Parameters` (expressions not allowed) `:`

i- Prefix Length

`Returns:` text_t

`*STARTSWITH_ANY` (text_t patset_name)

Results in Boolean TRUE value if the Text starts with any of the strings that are bound to the patset or dataset named by the string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` bool_at

`*STARTSWITH_INDEX` (text_t patset_name)

Returns the numerical index of the matching string, if the Text starts with any of the strings that are bound to the patset or dataset named by the string argument. Returns 0 if there is no match. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` num_at

`*STARTSWITH` (text_t start)

Results in Boolean TRUE value if a prefix of the Text object matches the string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

start- String

`Returns:` bool_at

`*STRIP_CHARS` (text_t s)

From the selected text remove the characters specified in the string.

For example: Say the selected text is / "foo.xyz=bar" /. Then on executing STRIP_CHARS('.=') or STRIP_CHARS('..=') the selected text will become /fooxyzbar /. Note that repeating character has same effect as it would be if it present only once. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*STRIP_END_CHARS` (text_t s)

Selects the Text after stripping off characters in the end of the current Text object.

For example: Say the selected text is / "foo.xyz=bar" /. Then on executing STRIP_END_CHARS('ar') the selected text will become /foo.xyz=b /. Note that repeating character has same effect as it would be if it present only once. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*STRIP_END_WS`

Selects the Text after stripping off white space in the end of the current Text object.

`Returns:` text_t

`*STRIP_START_CHARS` (text_t s)

Selects the Text after stripping off characters in the beginning of the current Text object.

For example: Say the selected text is / "foo.xyz=bar" /. Then on executing STRIP_START_CHARS('of') the selected text will become /.xyz=bar /. Note that repeating character has same effect as it would be if it present only once. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*STRIP_START_WS`

Selects the Text after stripping off white space in the beginning of the current Text object.

`Returns:` text_t

`*SUBSTR_ANY` (text_t patset_name)

Select any one sub-string that matches any string in the given patset or dataset. The patset cannot have strings longer than 255 characters. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` text_t

`*SUBSTR` (`uint` start, `uint` len)

Select the Text object of the given length at the given offset. Offset it 0 based. If there aren't enough characters after the offset then all the remaining characters are selected.

`Parameters``:`

start- Offset

len- Length

`Returns:` text_t

`*SUBSTR` (text_t s)

The SUBSTR operator in this object overrides the Text SUBSTR operator to operate on all the instances of the current header type. Selects Text that matches the input string argument. The order in which the instances of the header are matched is from the last instance to the first.

HTTP/1.1 200 OK\\r\\n MyHdr: 111abc\\r\\n Content-Length: 200\\r\\n MyHdr: 111def\\r\\n \\r\\n

For example: HTTP.RES.HEADER("MyHdr").SUBSTR("111") selects "111" in the last instance of MyHdr, the one with value "111def". This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*SUFFIX` (`char` c, `uint` i)

Select a suffix of the Text. The selected suffix is the longest possible suffix containing at most Count (2nd arg) occurrences of the character in the 1st argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

c- Character

i- Count

`Returns:` text_t

`*SUFFIX` (`uint` i)

Select a suffix of the Text. The length of the suffix is equal to the number in the argument. If there aren't enough characters in the Text object then the entire Text is selected.

`Parameters``:`

i- Suffix Length

`Returns:` text_t

`*TO_LOWER`

Converts the selected text to lower case.

For example, the string "ABCd" is converted to "abcd"

`Returns:` text_t

`*TO_UPPER`

Converts the selected text to upper case.

For example, the string "abcD" is converted to "ABCD"

`Returns:` text_t

`*TRUNCATE` (`char` c, `uint` i)

Select the Text after truncating a suffix from the current Text object. The truncated suffix is the longest possible suffix containing at most Count (2nd arg) occurrences of the character in the 1st argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

c- Character

i- Count

`Returns:` text_t

`*TRUNCATE` (`uint` i)

Select the Text after truncating a suffix of the Text. The length of the suffix truncated is equal to the number in the argument. If there aren't enough characters in the Text then then all the characters are truncated.

`Parameters``:`

i- Suffix Length

`Returns:` text_t

`*TYPECAST_AVP_T`

Convert text_t to avp_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (avp_t : Operations that can be performed on the returned AVPs.

`Note:` An AVP can have multiple instances in a Diameter message. However, the system can access only the first 16 instances.

`Example:`

- To get the first value of AVP code 266 from a request, use: DIAMETER.REQ.AVP(266).VALUE(0).
- To get the fourth value of AVP code 266 from a request, use: DIAMETER.REQ.AVP(266).VALUE(3).
- To check if AVP code 1000 in the response has the vendor-specific bit set, use: DIAMETER.RES.AVP(1000).IS_VENDOR_SPECIFIC.

)

`Returns:` avp_t

`*TYPECAST_AVP_UNUM_T`

Convert text_t to avp_unum_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (avp_unum_t : In Diameter AVP based expressions can be written as DIAMETER.REQ.AVP(<avpcode>). For example Auth-Application-Id AVP (AVP code 258) can be extracted as DIAMETER.REQ.AVP(258) For few of the important AVPs we provide aliases. For example this AVP based expression can also be written as DIAMETER.REQ.AUTH_APPLICATION_ID. This expression returns either a object of class avp_t

or returns a numerical value (object of class unsigned_long_at). The numerical value for this object is derived from the value in first instance of the AVP.)

`Returns:` avp_unum_t

`*TYPECAST_BOOL_AT`

Convert text_t to bool_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (bool_at : Boolean Operations)

`Returns:` bool_at

`*TYPECAST_COOKIE_T`

Convert text_t to cookie_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (cookie_t : The HTTP Cookie type provides operations for a cookie as it appears in the Set-Cookie and Set-Cookie2 header. In this type the Name-Value List operations are also available. The first delimiter is = and the element delimiter is ;. Multiple consecutive ; are treated as one. (Same as applying the method IGNORE_EMPTY_ELEMENTS on a Name-Value List.) You can use the Name-value List operations to access cookie attributes. The name comparison for all list operations is case insensitive. In this type Text operations are also available. Each cookie begins with a COOKIE_NAME=COOKIE_VALUE pair followed by zero or more semi-colon separated attribute-value pairs. If an attribute appears more than once in a cookie, the value associated with the first appearance of the attribute is returned.

Format Cookie: Cookie1=Value;Version=decimal;Value;Domain=Value;Path=Value)

`Returns:` cookie_t

`*TYPECAST_DIAMETER_FLAG_T`

Convert text_t to diameter_flag_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (diameter_flag_t : Provides operation to treat the underlying 1 byte as set of bit flags. then set/unset/test/reset_all operations can be done on flag)

`Returns:` diameter_flag_t

`*TYPECAST_DNS_DOMAINNAME_T`

Convert text_t to dns_domainname_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (dns_domainname_t : This object provides

operations for parsing the DNS domain name as it appears at various places in the DNS data. The format is abc.foo.com.)

`Returns:` dns_domainname_t

`*TYPECAST_DNS_FLAG_T`

Convert text_t to dns_flag_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (dns_flag_t : Provides operations to test/set/unset a flag in dns header.)

`Returns:` dns_flag_t

`*TYPECAST_DOUBLE_AT`

Convert text_t to double_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_at : Double Value)

`Returns:` double_at

`*TYPECAST_DOUBLE_T` (double_format_e format)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error.)

`Parameters` (expressions not allowed) `:`

format- Format

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, double_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one

or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, ip_address_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, num_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, time_local_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, time_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, unsigned_long_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the

beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_HTTP_CACHE_CONTROL_T`

Convert text_t to http_cache_control_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_cache_control_t : This object provides for the ability to work on HTTP Cache-Control headers. The name comparison for all list operations is case insensitive.)

`Returns:` http_cache_control_t

`*TYPECAST_HTTP_CONTENT_LENGTH_T`

Convert text_t to http_content_length_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_content_length_t : The HTTP.REQ.CONTENT_LENGTH or HTTP.RES.CONTENT_LENGTH object can be treated as a HTTP Header or as a Number. The numerical value for this object is derived from the value in the last instance of the Content-Length header.)

`Returns:` http_content_length_t

`*TYPECAST_HTTP_COOKIE_T`

Convert text_t to http_cookie_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_cookie_t : This object provides operations for parsing the HTTP cookie header. The name-value pair is derived from the value in the last instance of Cookie header. The format is Cookie : name0=value0; name1=value1; An HTTP Cookie header can have multiple occurrences. COUNT will return a Number containing how many headers of the current type exist. The name comparison for all list operations is case insensitive. The system does not keep track of more than 15 HTTP headers. The result will be undefined if there are more than 15 instances of the header.)

`Returns:` http_cookie_t

`*TYPECAST_HTTP_DATE_T`

Convert text_t to http_date_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_date_t : The HTTP.REQ.DATE or HTTP.RES.DATE object can be treated as a HTTP header or a Time object. The Time value is derived from the value in the last instance of the Date header. The date formats supported are RFC 822 (updated by RFC 1123), RFC 1036 (obsoletes RFC850) and ANSI C asctime() formats.)

`Returns:` http_date_t

`*TYPECAST_HTTP_HEADER_T` (text_t name)

Convert text_t to http_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_header_t : When typecasting a Text object to HTTP Header a header name must be provided.For example: HTTP.REQ.HEADER("MyHdr").TYPECAST_HTTP_HEADER_T("InHdr"))

`Parameters` (expressions not allowed) `:`

name- Header Name

`Returns:` http_header_t

`*TYPECAST_HTTP_HOSTNAME_T`

Convert text_t to http_hostname_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_hostname_t : This object provides operations for parsing the HTTP hostname as it appears at various places in the HTTP protocol data. The format is abc.foo.com:8080.)

`Returns:` http_hostname_t

`*TYPECAST_HTTP_METHOD_T`

Convert text_t to http_method_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_method_t : This object provides Text operations and HTTP Request Method Enum operations on the HTTP request method.)

`Returns:` http_method_t

`*TYPECAST_HTTP_SET_COOKIE_T`

Convert text_t to http_set_cookie_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_set_cookie_t : HTTP.RES.SET_COOKIE provides operations for parsing and operating on the SET-COOKIE header that is present in the HTTP response. HTTP Set-Cookie header supports Text and HTTP Header operations. For most Text operations the value in the last Set-Cookie header is selected. HTTP Set-Cookie header also supports special operations to extract cookies from the response. It is assumed that there will be only one cookie in a Set-Cookie header.)

`Returns:` http_set_cookie_t

`*TYPECAST_HTTP_URL_T`

Convert text_t to http_url_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_url_t : HTTP.REQ.URL provides operations for parsing and operating on the URL that is present in the first line of the HTTP request header. The supported format is \[<protocol>://<hostname>\]<path>?<query>. The Text object backing a HTTP URL object has the Text Mode set to URLENCODED by default.)

`Returns:` http_url_t

`*TYPECAST_HTTP_VERSION_T`

Convert text_t to http_version_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_version_t : HTTP.REQ.VERSION or HTTP.RES.VERSION provide operations to extract HTTP version information.)

`Returns:` http_version_t

`*TYPECAST_IPV6_ADDRESS_AT`

Convert text_t to ipv6_address_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ipv6_address_at : Provides operations for the 128-bit IPv6 address value. Some general information regarding IPv6 expressions: IPv6 PIXL expressions can be combined with other PIXL expressions using the '+' operator. The output is expected to be the concatenation of the string representations of the individual PIXL expressions. No other operator other than '+' is expected to work when any of the operands is an IPv6 PIXL expression. Also, IPv6 PIXL expressions can be combined with any other type of PIXL expression except a PIXL expression that produces a bool result. In other words, if A and/or B are two IPv6 addresses, A+B should result in the string AB. When one of A or B is an IPv6 address, the other can only be a

number or a string and not a boolean. Further, when A and/or B is an IPv6 address, the only operator allowed between them is '+'.

Example: Let the client source IPv6 address be ABCD:1234::ABCD. Let the server destination IPv4 address be 10.100.10.100. Then the expression CLIENT.IPV6.SRC + SERVER.IP.DST should produce the output "ABCD:1234::ABCD10.100.10.100". Similarly, CLIENT.IPV6.SRC + 5 should produce the result ABCD:1234::ABCD5)

`Returns:` ipv6_address_at

`*TYPECAST_IPV6_ADDRESS_T`

Convert text_t to ipv6_address_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ipv6_address_t : This object represents an IPv6 address present in the 1000:1001:CD10:0000:0000:89AB:4567:CDEF format.)

`Returns:` ipv6_address_t

`*TYPECAST_IPV6_SUBNET_AT`

Convert text_t to ipv6_subnet_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ipv6_subnet_at : Provides operations for the integral IPv6 subnet address value.)

`Returns:` ipv6_subnet_at

`*TYPECAST_IPV6_SUBNET_T`

Convert text_t to ipv6_subnet_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ipv6_subnet_t : This object represents an IPv6 subnet address present in the 1000:1001:CD10:0000:0000:89AB:4567:CDEF/64 format.)

`Returns:` ipv6_subnet_t

`*TYPECAST_IP_ADDRESS_AT`

Convert text_t to ip_address_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ip_address_at : Provides operations for the 32-bit integral IP address value.)

`Returns:` ip_address_at

`*TYPECAST_IP_ADDRESS_T`

Convert text_t to ip_address_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ip_address_t : Represents an IP address present in the 10.100.200.1 format.)

`Returns:` ip_address_t

`*TYPECAST_IP_OPTIONS_T`

Convert text_t to ip_options_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ip_options_t : IP protocol options)

`Returns:` ip_options_t

`*TYPECAST_IP_OPTIONS_TYPE_T`

Convert text_t to ip_options_type_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ip_options_type_t : IP Options Type)

`Returns:` ip_options_type_t

`*TYPECAST_IP_TOS_T`

Convert text_t to ip_tos_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ip_tos_t : Provides operations to TOS field in IP header.)

`Returns:` ip_tos_t

`*TYPECAST_LIST_T` (`char` sep)

Convert text_t to list_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (list_t : The character separator has to be provided when typecasting a textual context to list type. The current text mode has no effect on the character separator. For example if the current text mode is IGNORECASE and the separator is p then P will not be treated as a separator.)

`Parameters` (expressions not allowed) `:`

sep- Separator

`Returns:` list_t

`*TYPECAST_MAC_ADDRESS_AT`

Convert text_t to mac_address_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (mac_address_at : Provides operations for the 48-bit MAC address value.)

`Returns:` mac_address_at

`*TYPECAST_MAC_ADDRESS_T`

Convert text_t to mac_address_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (mac_address_t : Represents a MAC address present in the 12:34:56:78:9a:bc format.)

`Returns:` mac_address_t

`*TYPECAST_NUM_AT`

Convert text_t to num_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (num_at : Number Value)

`Returns:` num_at

`*TYPECAST_NUM_T` (num_format_e format)

Convert text_t to num_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (num_t : Treat the underlying text as a Number in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error.)

`Parameters` (expressions not allowed) `:`

format- Format

`Returns:` num_t

`*TYPECAST_NUM_T` (num_format_e format, num_at default_value)

Convert text_t to num_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (num_t : Treat the underlying text as a Number in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL

and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` num_t

`*TYPECAST_NVLIST_T` (`char` sep1, `char` sep2)

Convert text_t to nvlist_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (nvlist_t : Two character delimiters have to be provided when typecasting a Text object to a Name-Value List. The first delimited separates the name from the value. The second delimiter separates list items. For example typecast_nvlist_t('=', '&') handles a URL query string. The Text Mode has no effect on the character delimiters. For example if the current text mode is IGNORECASE and a delimiter is p then P will not be treated as a delimiter.)

`Parameters` (expressions not allowed) `:`

sep1- delimiter1

sep2- delimiter2

`Returns:` nvlist_t

`*TYPECAST_NVLIST_T` (`char` sep1, `char` sep2, `char` quote)

Convert text_t to nvlist_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (nvlist_t : Two character delimiters and quote-character have to be provided when typecasting a Text object to a Name-Value List that supports quote-character. The first delimited separates the name from the value. The second delimiter separates list items. The third value specifies the quote character. For example typecast_nvlist_t('=', ';', "") handles a name-value list separated by semi-colons that allows quoting. The quote-character specifies that the value can occur within the quotes and the delimiters within the quote-characters should not be taken into account. The Text Mode has no effect on the character delimiters. For example if the current text mode is IGNORECASE and a delimiter is p then P will not be treated as a delimiter.)

`Parameters` (expressions not allowed) `:`

sep1- delimiter1

sep2- delimiter2

quote- quote-character.

`Returns:` nvlist_t

`*TYPECAST_PROTOCOL_BUFFER_T`

Convert text_t to protocol_buffer_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (protocol_buffer_t : gRPC Protocol Buffers interface)

`Returns:` protocol_buffer_t

`*TYPECAST_RADIUS_AVP_T`

Convert text_t to radius_avp_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (radius_avp_t : Operations that can be performed on the returned AVPs.

`Note:` An AVP can have multiple instances in a radius message. However, the system can access only the first 16 instances.

`Example:`

- To get the first value of AVP code 26 from a request, use: radius.REQ.AVP(26).VALUE(0).
- To get the fourth value of AVP code 26 from a request, use: radius.REQ.AVP(26).VALUE(3).

)

`Returns:` radius_avp_t

`*TYPECAST_RADIUS_AVP_VALUE_T`

Convert text_t to radius_avp_value_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (radius_avp_value_t : Provides operations to typecast RADIUS AVP value to Integer value or IP Address.)

`Returns:` radius_avp_value_t

`*TYPECAST_SEQ_TEXT_T`

Convert text_t to seq_text_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (seq_text_t : Represents the Text Sequence class.)

`Returns:` seq_text_t

`*TYPECAST_SERVICEPATH_T`

Convert text_t to servicepath_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (servicepath_t : Operations that can be performed on the service path.

`Example:`

- To get the name of the service path applicable to current subscriber, use: SUBSCRIBER.SERVICEPATH
- To determine If the service function is the next in the service path applicable to scubscriber, use: SUBSCRIBER.SERVICEPATH.IS_NEXT().

)

`Returns:` servicepath_t

`*TYPECAST_SIP_CALLID_HEADER_T`

Convert text_t to sip_callid_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_callid_header_t : This object provides operations for parsing the SIP callid header.)

`Returns:` sip_callid_header_t

`*TYPECAST_SIP_CONTENT_LENGTH_T`

Convert text_t to sip_content_length_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_content_length_t : The SIP.REQ.CONTENT_LENGTH or SIP.RES.CONTENT_LENGTH object can be treated as a SIP Header or as a Number. The numerical value for this object is derived from the value in the last instance of the Content-Length header.)

`Returns:` sip_content_length_t

`*TYPECAST_SIP_FROM_HEADER_T`

Convert text_t to sip_from_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_from_header_t : This object provides operations for parsing the SIP From header.)

`Returns:` sip_from_header_t

`*TYPECAST_SIP_HEADER_T` (text_t name)

Convert text_t to sip_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_header_t : When typecasting a Text object to SIP Header a header name must be provided.For example: SIP.REQ.HEADER("MyHdr").TYPECAST_SIP_HEADER_T("InHdr"))

`Parameters` (expressions not allowed) `:`

name- Header Name

`Returns:` sip_header_t

`*TYPECAST_SIP_HOSTNAME_T`

Convert text_t to sip_hostname_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_hostname_t : This object provides operations for parsing the SIP hostname as it appears at various places in the SIP protocol data. The format is abc.foo.com:5060.)

`Returns:` sip_hostname_t

`*TYPECAST_SIP_METHOD_T`

Convert text_t to sip_method_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_method_t : This object provides Text operations and SIP Request Method Enum operations on the SIP request method.)

`Returns:` sip_method_t

`*TYPECAST_SIP_TO_HEADER_T`

Convert text_t to sip_to_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_to_header_t : This object provides operations for parsing the SIP From header.)

`Returns:` sip_to_header_t

`*TYPECAST_SIP_URL_T`

Convert text_t to sip_url_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_url_t : SIP.REQ.URL provides operations for parsing and operating on the URL that is present in the first line of the SIP request header. The supported format is \[<protocol>://<hostname>\]<path>?<query>. The Text object backing a SIP URL object has the Text Mode set to URLENCODED by default.)

`Returns:` sip_url_t

`*TYPECAST_SIP_VERSION_T`

Convert text_t to sip_version_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_version_t : SIP.REQ.VERSION or SIP.RES.VERSION provide operations to extract SIP version information.)

`Returns:` sip_version_t

`*TYPECAST_SIP_VIA_HEADER_T`

Convert text_t to sip_via_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_via_header_t : This object provides operations for parsing the SIP Via header.)

`Returns:` sip_via_header_t

`*TYPECAST_SSLVPN_MODE_T`

Convert text_t to sslvpn_mode_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sslvpn_mode_t : This object provides Text operations and SSLVPN Mode Enum operations on the SSLVPN request method.)

`Returns:` sslvpn_mode_t

`*TYPECAST_SSL_TEXT_T` (text_t name)

Convert text_t to ssl_text_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ssl_text_t : Treat the underlying text object as SSL Text.)

`Parameters` (expressions not allowed) `:`

name- Name

`Returns:` ssl_text_t

`*TYPECAST_TCP_OPTIONS_T`

Convert text_t to tcp_options_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (tcp_options_t : TCP Protocol Options)

`Returns:` tcp_options_t

`*TYPECAST_TCP_OPTIONS_TYPE_T`

Convert text_t to tcp_options_type_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (tcp_options_type_t : TCP Protocol Options Type)

`Returns:` tcp_options_type_t

`*TYPECAST_TCP_REPEATER_OPTION_T`

Convert text_t to tcp_repeater_option_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (tcp_repeater_option_t : TCP Protocol Option : Repeater)

`Returns:` tcp_repeater_option_t

`*TYPECAST_TEXT_T`

Convert http_header_t to text_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (text_t : Designates any piece of text.)

`Returns:` text_t

`*TYPECAST_TIME_AT`

Convert text_t to time_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (time_at : Treats a number value as number of seconds since GMT Jan 1 1970 0h 0m 0s.)

`Returns:` time_at

`*TYPECAST_TIME_LOCAL_AT`

Convert text_t to time_local_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (time_local_at : Treats a number value as number of seconds since GMT Jan 1 1970 0h 0m 0s as adjsuted for the local time zone.)

`Returns:` time_local_at

`*TYPECAST_TIME_T`

Convert text_t to time_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (time_t : This object treats a Text object as a date string. The formats supported are

1\. RFC822 :: Sun, 06 Nov 1994 08:49:37 GMT 2\. RFC850 :: Sunday, 06-Nov-94 08:49:37 GMT 3\. ASCTIME :: Sun Nov 6 08:49:37 1994 4\. ASCTIME like :: Sun Nov 6 08:49:37 1994 5\. ASCTIME like :: Sun Nov 06 08:49:37 1994 6\. Http Set-Cookie Expiry date :: Sun, 06-Nov-1994 08:49:37 GMT)

`Returns:` time_t

`*TYPECAST_UNSIGNED_LONG_AT`

Convert text_t to unsigned_long_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_at : Unsigned Long(64bit) Value)

`Returns:` unsigned_long_at

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error.)

`Parameters` (expressions not allowed) `:`

format- Format

`Returns:` unsigned_long_t

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format, ip_address_at default_value)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining

characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` unsigned_long_t

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format, unsigned_long_at default_value)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` unsigned_long_t

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format, num_at default_value)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` unsigned_long_t

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format, time_local_at default_value)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` unsigned_long_t

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format, time_at default_value)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` unsigned_long_t

`*TYPECAST_UNUM_TEXT_T`

Convert text_t to unum_text_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unum_text_t : Provides operations to treat the underlying OctectString as Binary String or unsigned long value .)

`Returns:` unum_text_t

`*TYPECAST_URL_CATEGORY_T`

Convert text_t to url_category_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (url_category_t : Retrieves URL category and attributes from an URL)

`Returns:` url_category_t

`*TYPECAST_VENDOR_SPEC_APPID_AVP_T`

Convert text_t to vendor_spec_appid_avp_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (vendor_spec_appid_avp_t : Retrieves AVPs that are nested in the grouped AVP Vendor-Specific-Application-Id (code 260). The nested AVPs are:

- Vendor-Id
- Auth-Application-Id
- Acct-Application-Id

For example, to retrieve the Auth-Application-Id AVP from the Vendor-Specific-Application-Id AVP:

- For requests: DIAMETER.REQ.VENDOR_SPECIFIC_APPLICATION_ID.AUTH_APPLICATION_ID
- For responses: DIAMETER.RES.VENDOR_SPECIFIC_APPLICATION_ID.AUTH_APPLICATION_ID

)

`Returns:` vendor_spec_appid_avp_t

`*TYPECAST_VENDOR_SPEC_RADIUS_AVP_T`

Convert text_t to vendor_spec_radius_avp_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (vendor_spec_radius_avp_t :

- Vendor-Id

To retrieve the Vendor-Id from the Vendor-Specific AVP:

- RADIUS.REQ.VENDOR_SPECIFIC.VENDORID

)

`Returns:` vendor_spec_radius_avp_t

`*UNQUOTE` (`char` c)

If selected text is quoted by character c, Remove character c from beginning and end.

For example: Say the selected text is / "foo xyz bar " /. Then on executing UNQUOTE("") the selected text will become /foo xyz bar / This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

c- Character

`Returns:` text_t

`*URLSET_MATCHES_ANY` (text_t urlset_name)

Results in Boolean TRUE value if and only if the Text matches any of the patterns that are specified in the urlset named by the string argument. The matching is case-insensitive for domains, but case-sensitive for paths. For example:

- HTTP.REQ.HOST.APPEND(HTTP.REQ.URL).URLSET_MATCHES_ANY("urlset_forbidden") returns true when the combined domain and URL matches any pattern in the urlset whose name is "urlset_forbidden".

`Parameters` (expressions not allowed) `:`

urlset_name- urlset name

`Returns:` bool_at

`*URL_CATEGORIZE` (`uint` min_reputation, `uint` max_reputation)

Returns the URL category for the supplied URL with the given minimum and maximum reputation score. Where a score of 5 is most risky and 1 is least risky. If either score is set to 0, that bound would be ignored. By specifying the reputation scores, the function will returned the category with the highest score (most risky) based on the bounds. If there was an error getting the category or if the URL is invalid then it will result in an Undef error. For example: HTTP.REQ.HOST.APPEND(HTTP.REQ.URL).URL_CATEGORIZE(0, 0) returns value when the combined domain and URL is looked up for the URL category with the highest reputation score (most risky).

`Parameters` (expressions not allowed) `:`

min_reputation- Minimum reputation score of URL category

max_reputation- Maximum reputation score of URL category

`Returns:` url_category_t

`*URL_RESERVED_CHARS_SAFE`

Converts URL reserved characters to corresponding '%XX' values and retains the rest. This is a read only operation.

```
Based on RFC3986, following are considered URL unreserved characters:

    Alpha-numeric characters: a-z, A-Z, 0-9

    Hyphen and underscore: "-", "_"

    Dot: "."

    Tilde: "~"
```

The rest are converted to %XX encoding, 'XX' is the hex-based representation of the input character. If the requirement is to encode all but URL safe characters, please consider using HTTP_URL_SAFE method.

`Returns:` text_t

`*VALUES`

Extracts a list of only the values from the name-value pair list. For example the list 'a=b,c=d,e=f' will result in the list 'b,d,f'. Note that lists do not honor the quote characters, so any nvlist_at entry that

has quotes and a quoted entry includes a separator will be split at that embedded separator. Quote characters will not be stripped from the values. Empty elements and empty values will be ignored.

`Returns:` list_t

`*VALUE` (`uint` i)

Operate as Text on the value component of the specified name-value component in the list. The index of the name-value component given by the argument is 0-based. If the specified index is greater than the number of components then a zero length Text object is produced.

`Parameters` (expressions not allowed) `:`

i- Index

`Returns:` text_t

`*VALUE` (text_t name)

Operate as Text on the value component of the specified name-value component in the list. The name-value component is specified by the argument by providing the name whose value is needed. The first component that matches the name is selected. The matching process honors the IGNORECASE and the NOIGNORECASE text modes. The URLENCODED and the NOURLENCODED text modes are ignored.

`Parameters` (expressions not allowed) `:`

name- Name

`Returns:` text_t

`*VALUE` (text_t name, `uint` i)

Operate as Text on the value component of the specified name-value component in the list. The name-value component is specified by the argument by providing the name whose value is needed. In a name-value list the same name can be repeated multiple times. The Index argument controls which occurence of the matching name-value component should be selected. The Index is 0-based. If the Index is too big then the Text object that is produced will have zero length. The matching process honors the IGNORECASE and the NOIGNORECASE text modes. The URLENCODED and the NOURLENCODED text modes are ignored.

`Parameters` (expressions not allowed) `:`

name- Name

i- Index

`Returns:` text_t

`*XML_DECRYPT` (text_t certKeyName)

Decrypt the selected content, which was encrypted using the W3C XML Encryption standard.

`Parameters` (expressions not allowed) `:`

certKeyName- identifies the certkey object containing the RSA private key to be used to decrypt the bulk encryption key in the selected EncryptedData element.

`Returns:` text_t

`*XML_ENCRYPT` (text_t certKeyName, encrypt_method_e method)

Encrypt the selected cleartext using the W3C XML Encryption standard.

`Parameters` (expressions not allowed) `:`

certKeyName- identifies the certkey object containing an X.509 certificate with the RSA public key to be used to encrypt the generated bulk encryption key. Note that the certKey object need not, and usually will not, include the associated RSA private key.

method- specifies the bulk encryption method (rc4, des3, aes128, aes192, or aes256) used to encrypt the content.

`Returns:` text_t

`*XML_ENCRYPT` (text_t certKeyName, encrypt_method_e method, `uint` flags)

Encrypt the selected cleartext using the W3C XML Encryption standard.

`Parameters` (expressions not allowed) `:`

certKeyName- identifies the certkey object containing an X.509 certificate with the RSA public key to be used to encrypt the generated bulk encryption key. Note that the certKey object need not, and usually will not, include the associated RSA private key.

method- specifies the bulk encryption method (rc4, des3, aes128, aes192, or aes256) used to encrypt the content.

flags- optional bit mask to specify optional elements in the EncryptedData element. These are hints to tell the receiver what private key to use to decrypt the bulk encryption key, providing information from the certKey's X.509 certificate.

- 1 - include a KeyName element with the certKeyName;
- 2 - include a KeyValue element with the RSA public key from the certificate;
- 4 - include an X509IssuerSerial element with the certificate serial number and issuer DN;
- 8 - include an X509SubjectName element with the certificate subject DN;
- 16 - include an X509Certificate element with the entire certificate;

`Returns:` text_t

`*XPATH_HTML_WITH_MARKUP` (`xpath_str` xpathex)

Applies an XPath expression to the DOM for an HTML document and returns the selected node-set or string, including markup like element tags. node-sets are converted to strings using the standard XPath string conversion routine. The selected portion of the document can be used as the target for rewrite actions.

Examples: HTTP.REQ.BODY(1000).XPATH_HTML_WITH_MARKUP(xp%//md/head/title%) returns the <title> element in the document's <head> This can be used in a rewrite action to replace or delete the <title> element.

`Parameters` (expressions not allowed) `:`

xpathex- XPath Expression

`Returns:` text_t

`*XPATH_HTML` (`xpath_bool` xpathex)

Applies an XPath expression to the DOM for an HTML document and a boolean value.

Examples: HTTP.RES.BODY(1000).XPATH_HTML(xp%boolean(/md/head/meta)%) returns true if the <meta> element exists as a child of <head> element.

`Parameters` (expressions not allowed) `:`

xpathex- XPath Expression

`Returns:` bool_at

`*XPATH_HTML` (`xpath_double` xpathex)

Applies an XPath expression to the DOM for an HTML document and a double value.

Examples: HTTP.RES.BODY(1000).XPATH_HTML(xp%number(//video/@height)%) returns the numeric value of the height attribute of the first <video> element.

`Parameters` (expressions not allowed) `:`

xpathex- XPath Expression

`Returns:` double_at

`*XPATH_HTML` (`xpath_str` xpathex)

Applies an XPath expression to the DOM for an HTML document and returns the selected node-set or string. node-sets are converted to strings using the standard XPath string conversion routine.

Examples: HTTP.REQ.BODY(1000).XPATH_HTML(xp%//img/@src%) returns the string value of the src attribute of the first

HTTP_CONTENT_LENGTH_T

The HTTP.REQ.CONTENT_LENGTH or HTTP.RES.CONTENT_LENGTH object can be treated as a HTTP Header or as a Number. The numerical value for this object is derived from the value in the last instance of the Content-Length header.

This topic lists the expressions that are provided by this class.

`*Note` *: Expressions with the * symbol are inherited / promoted from http_header_t num_at

- `TYPECAST_HTTP_HEADER_T`

  Convert http_content_length_t to http_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_header_t : Typecast an HTTP Header object of a specific type to HTTP Header.For example: HTTP.REQ.CONTENT_LENGTH.TYPECAST_HTTP_HEADER_T)

`Returns:` http_header_t

`*TYPECAST_NUM_AT`

Convert http_content_length_t to num_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (num_at : Number Value)

`Returns:` num_at

`*ABS`

Return the absolute value of the number.

`Returns:` num_at

`*ADD` (double_at i)

Return the Double Value after adding the argument to the current double value.

`Parameters``:`

i- Double

`Returns:` double_at

`*ADD` (ip_address_at i)

Return the Unsigned Long after adding the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*ADD` (unsigned_long_at i)

Return the Unsigned Long after adding the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*ADD` (num_at i)

Return the Number Value after adding the argument to the current number value.

`Parameters``:`

i- Number

`Returns:` num_at

`*ADD` (time_local_at i)

Return the Unsigned Long after adding the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*ADD` (time_at i)

Return the Unsigned Long after adding the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*AFTER_REGEX` (`re` regex)

The AFTER_REGEX operator in this object overrides the Text AFTER_REGEX operator to operate on all the instances of the current header type. Selects the Text after the text that matches the input regular expression in any instance of the header value. The order in which the header instances will be matched is from the last to the first.

For example: HTTP.REQ.HEADER("etag").AFTER_REGEX(re/KX/) will select "DAPPER" from "KXDAPPER". This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

regex- Regular Expression

`Returns:` text_t

`*AFTER_STR_ANY` (text_t patset_name)

Selects the Text that is present after the first occurrence of any of the strings that are bound to the patset named by the string argument. If there is no match to any of the strings bound to the patset in the current Text object then the result Text object has 0 length. The patset cannot have strings longer than 255 characters. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` text_t

`*AFTER_STR` (text_t s)

The AFTER_STR operator in this object overrides the Text AFTER_STR operator to operate on all the instances of the current header type. Selects Text after the first occurrence of the input string argument. The order in which the instances of the header are matched is from the last instance to the first.

HTTP/1.1 200 OK\\r\\n MyHdr: 111abc\\r\\n Content-Length: 200\\r\\n MyHdr: 111def\\r\\n \\r\\n

Examples: HTTP.RES.HEADER("MyHdr").AFTER_STR("111") selects "def" in the last instance of MyHdr, the one with value "111def". HTTP.RES.HEADER("MyHdr").AFTER_STR("1ab") selects "c" in the first instance of MyHdr, the one with value "abc111". This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*APPEND` (bool_at b)

Appends the given boolean's string representation to the current string.

`Parameters``:`

b- the boolean value to append.

`Returns:` text_t

`*APPEND` (double_at i)

Appends the given double's string representation to the current string.

`Parameters``:`

i- the double value to append.

`Returns:` text_t

`*APPEND` (ip_address_at addr)

Appends the given IPv4's string representation to the current string.

`Parameters``:`

addr- the IPv4 address to append.

`Returns:` text_t

`*APPEND` (num_at i)

Appends the given number's string representation to the current string.

`Parameters``:`

i- the number value to append.

`Returns:` text_t

`*APPEND` (time_local_at t)

Appends the given time's string representation to the current string.

`Parameters``:`

t- the time value to append.

`Returns:` text_t

`*APPEND` (time_at t)

Appends the given time's string representation to the current string.

`Parameters``:`

t- the time value to append.

`Returns:` text_t

`*APPEND` (unsigned_long_at i)

Appends the given unsigned long's string representation to the current string.

`Parameters``:`

i- the unsigned long value to append.

`Returns:` text_t

`*APPEND` (ipv6_address_at addr)

Appends the given IPv6's string representation to the current string.

`Parameters``:`

addr- the IPv6 address to append.

`Returns:` text_t

`*APPEND` (ipv6_subnet_at addr)

Appends the given IPv6 subnet's string representation to the current string.

`Parameters``:`

addr- the IPv6 subnet to append.

`Returns:` text_t

`*APPEND` (mac_address_at addr)

Appends the given MAC's string representation to the current string.

`Parameters``:`

addr- the MAC address to append.

`Returns:` text_t

`*APPEND` (text_t str)

Appends the given string to the string representation of the current number.

`Parameters``:`

str- the string to append.

`Returns:` text_t

`*APPEND` (time_at t)

Appends the given time's string representation to the current string.

`Parameters``:`

t- the time value to append.

`Returns:` text_t

`*AS_MICROSEC_STR`

Returns the current system time in the following format Format: Wday, day Month year hh:mm:ss.ffffff GMT ffffff represents microseconds Examples:

Mon, 05 Mar 2018 10:23:36.568419 GMT

`Returns:` text_t

`*AS_MILLISEC_STR`

Returns the current system time in the following format Format: Wday, day Month year hh:mm:ss.fff GMT fff represents milliseconds Examples:

Mon, 05 Mar 2018 10:23:36.568 GMT

`Returns:` text_t

`*AS_NANOSEC_STR`

Returns the current system time in the following format Format: Wday, day Month year hh:mm:ss.fffffffff GMT fffffffff represents nanoseconds Accuracy may be at larger granularity than nanosecond resolution. Examples:

Mon, 05 Mar 2018 10:23:36.568419567 GMT

`Returns:` text_t

`*B64DECODE`

Decodes the selected text using base64 decoding.

For example, the string "TWFu" is converted to "Man"

`Returns:` text_t

`*B64ENCODE`

Encodes the selected text using base64 encoding.

For example, the string "Man" is converted to "TWFu"

`Returns:` text_t

`*BEFORE_REGEX` (`re` regex)

The BEFORE_REGEX operator in this object overrides the Text BEFORE_REGEX operator to operate on all the instances of the current header type. Selects the Text before the text that matches the input regular expression in any instance of the header value. The order in which the header instances will be matched is from the last to the first.

For example: HTTP.RES.HEADER("content-type").BEFORE_REGEX(re#/#) will select "text" from "text/plain". This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

regex- Regular Expression

`Returns:` text_t

`*BEFORE_STR_ANY` (text_t patset_name)

Selects the Text that is present before the first occurrence of any of the strings that are bound to the patset or datasetnamed by the string argument. If there is no match to any of the strings bound to the patset in the current Text object then the result Text object has 0 length. The patset cannot have strings longer than 255 characters. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` text_t

`*BEFORE_STR` (text_t s)

The BEFORE_STR operator in this object overrides the Text BEFORE_STR operator to operate on all the instances of the current header type. Selects Text before the first occurrence of the input string argument. The order in which the instances of the header are matched is from the last instance to the first.

HTTP/1.1 200 OK\\r\\n MyHdr: abc111\\r\\n Content-Length: 200\\r\\n MyHdr: def111\\r\\n \\r\\n

Examples: HTTP.RES.HEADER("MyHdr").BEFORE_STR("111") selects "def" in the last instance of MyHdr, the one with value "def111". HTTP.RES.HEADER("MyHdr").BEFORE_STR("bc1") selects "a" in the first instance of MyHdr, the one with value "abc111". This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*BETWEEN` (double_at i, double_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (double_at i, ip_address_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (double_at i, unsigned_long_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (ip_address_at i, double_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (ip_address_at i, ip_address_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (ip_address_at i, unsigned_long_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (unsigned_long_at i, double_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (unsigned_long_at i, ip_address_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (unsigned_long_at i, unsigned_long_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (double_at i, num_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (ip_address_at i, num_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (unsigned_long_at i, num_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (double_at i, time_local_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (ip_address_at i, time_local_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (unsigned_long_at i, time_local_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (double_at i, time_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (ip_address_at i, time_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (unsigned_long_at i, time_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (num_at i, double_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (num_at i, ip_address_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (num_at i, unsigned_long_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (num_at i, num_at j)

Returns Boolean TRUE if the number value is greater than or equal to the Lower argument and the number value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (num_at i, time_local_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (num_at i, time_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (text_t start, text_t end)

Results in Boolean TRUE value if length of the Text object is greater than or equal to the sum of the Start and End argument lengths and if the prefix of the Text object matches the Start string argument and if the Suffix of the Text object matches the End string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

start- Start

end- End

`Returns:` bool_at

`*BETWEEN` (time_local_at i, double_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (time_local_at i, ip_address_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (time_local_at i, unsigned_long_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (time_local_at i, num_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (time_local_at i, time_local_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (time_local_at i, time_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (time_at i, double_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (time_at i, ip_address_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (time_at i, unsigned_long_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (time_at i, num_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (time_at i, time_local_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (time_at i, time_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BIN_DECODE` (binary_encoding_e encoding)

Decode the encoded input into its original byte sequence. An incorrectly enooded input will result in an Undef error.

`Parameters` (expressions not allowed) `:`

encoding- specifies how the bytes are encoded.

`Returns:` text_t

`*BIN_ENCODE` (binary_encoding_e encoding)

Encode the input byte sequence. Note that BIN_ENCODE(hex_colons) is equivalent to BLOB_TO_HEX().

`Parameters` (expressions not allowed) `:`

encoding- specifies how the bytes are to be encoded.

`Returns:` text_t

`*BITAND` (ip_address_at i)

Return the Unsigned Long Value after bitwise ANDing the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*BITAND` (unsigned_long_at i)

Return the Unsigned Long Value after bitwise ANDing the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*BITAND` (num_at i)

Return the Number Value after bitwise ANDing the argument to the current number value.

`Parameters``:`

i- Number

`Returns:` num_at

`*BITAND` (time_local_at i)

Return the Unsigned Long Value after bitwise ANDing the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*BITAND` (time_at i)

Return the Unsigned Long Value after bitwise ANDing the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*BITNEG`

Return the Number Value after bitwise negating the current number value.

`Returns:` num_at

`*BITOR` (ip_address_at i)

Return the Unsigned Long Value after bitwise ORing the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*BITOR` (unsigned_long_at i)

Return the Unsigned Long Value after bitwise ORing the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*BITOR` (num_at i)

Return the Number Value after bitwise ORing the argument to the current number value.

`Parameters``:`

i- Number

`Returns:` num_at

`*BITOR` (time_local_at i)

Return the Unsigned Long Value after bitwise ORing the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*BITOR` (time_at i)

Return the Unsigned Long Value after bitwise ORing the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*BITXOR` (ip_address_at i)

Return the Unsigned Long Value after bitwise XORing the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*BITXOR` (unsigned_long_at i)

Return the Unsigned Long Value after bitwise XORing the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*BITXOR` (num_at i)

Return the Number Value after bitwise XORing the argument to the current number value.

`Parameters``:`

i- Number

`Returns:` num_at

`*BITXOR` (time_local_at i)

Return the Unsigned Long Value after bitwise XORing the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*BITXOR` (time_at i)

Return the Unsigned Long Value after bitwise XORing the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*BLOB_TO_HEX`

Convert to hexadecimal representation and select text.

For example, the byte string abc is converted to 61:62:63.

`Returns:` text_t

`*COMPARE` (text_t s)

Results in a Number Value which is the result of comparison of the input argument with the Text object. The result is greater than 0 if the Text object is lexicographically greater than the argument. The result is 0 if the Text object and the argument match. The result is less than 0 if the Text object is lexicographically lesser than the argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` num_at

`*CONTAINS_ANY` (text_t patclass_name)

The CONTAINS_ANY in this object overrides the Text CONTAINS_ANY operator to operate on all the instances of the current header type. Returns Boolean TRUE if any of the patterns associated with input patclass is present in any instance of the header value. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patclass_name- Patclass Name

`Returns:` bool_at

`*CONTAINS_INDEX` (text_t patclass_name)

The CONTAINS_INDEX in this object overrides the Text CONTAINS_INDEX operator to operate on all the instances of the current header type. Returns the index of the matching pattern associated with input patclass that is present in any instance of the header value. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patclass_name- Patclass Name

`Returns:` num_at

`*CONTAINS` (text_t s)

The CONTAINS in this object overrides the Text CONTAINS operator to operate on all the instances of the current header type. Returns Boolean TRUE if the input Pattern String is present in any instance of the header value.

GET / HTTP/1.1\\r\\n Host: abc.com\\r\\n MyHdr: abc\\r\\n Content-Length: 200\\r\\n MyHdr: def\\r\\n

HTTP/1.1 200 OK\\r\\n MyHdr: abc\\r\\n Content-Length: 200\\r\\n MyHdr: def\\r\\n \\r\\n

Examples: HTTP.RES.HEADER("MyHdr").CONTAINS("de") is TRUE.
HTTP.RES.HEADER("MyHdr").CONTAINS("bcd") is FALSE.
HTTP.REQ.HEADER("MyHdr").CONTAINS("de") is TRUE.
HTTP.REQ.HEADER("MyHdr").CONTAINS("bcd") is FALSE. The system does not concatenate the different values. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- Pattern String

`Returns:` bool_at

`*COUNT`

An HTTP header can have multiple occurrences. COUNT will return a Number containing how many headers of the current type exist.

HTTP/1.1 200 OK\\r\\n MyHdr: abc\\r\\n Content-Length: 200\\r\\n MyHdr: def\\r\\n \\r\\n

For example: HTTP.RES.HEADER("MyHdr").COUNT will return Number 2. The system does not keep track of more than 15 HTTP headers. The result will be undefined if there are more than 15 instances of the header.

`Returns:` num_at

`*CRC32`

Returns a 32-bit integer computed by applying a CRC (cyclic redundancy check) function to the selected text. This is the CRC function used by Ethernet, MPEG-2, PKZIP, GZIP, PNG, and many other applications. For example, the expression to compute the CRC value of the (first 1000 bytes of the) body of an HTTP request is: HTTP.REQ.BODY(1000).CRC32

`Returns:` num_at

`*DECODE_USING_TEXT_MODE`

Decodes the selected text using the currently configured text encoding methods like URLENCODED, BACKSLASH_ENCODED, PLUS_AS_SPACE, NOURLENCODED, NO_BACKSLASH_ENCODED and NO_PLUS_AS_SPACE. Text encoding methods are set using SET_TEXT_MODE method.

`Returns:` text_t

`*DECRYPT`

Decrypt the selected base64-encoded ciphertext using the configured encryptionParams.

`Returns:` text_t

`*DECRYPT` (binary_encoding_e in_encoding)

Decrypt the selected ciphertext using the configured encryptionParams.

`Parameters` (expressions not allowed) `:`

in_encoding- specifies how the input ciphertext is encoded. If the ciphertext is not encoded as specified, causes an Undef error.

`Returns:` text_t

`*DECRYPT` (text_t encryptionKey)

Decrypt the selected base64-encoded encrypted bytes using the configured encryption key.

`Parameters` (expressions not allowed) `:`

encryptionKey- identifies the encryptionKey object to provide the cipher method, mode, padding, key, encrypted format and optional initialization vector (IV).

`Returns:` text_t

`*DECRYPT` (text_t encryptionKey, binary_encoding_e in_encoding)

Decrypt the selected base64-encoded encrypted bytes using the configured encryption key.

`Parameters` (expressions not allowed) `:`

encryptionKey- identifies the encryptionKey object to provide the cipher method, mode, padding, key, encrypted format, and optional initialization vector (IV).

in_encoding- specifies how the input ciphertext is encoded. If the ciphertext is not encoded as specified, causes an Undef error.

`Returns:` text_t

`*DIGEST` (digest_method_e method)

Returns a byte sequence computed by applying the the specified message digest method to the selected text.

`Parameters` (expressions not allowed) `:`

method- digest method to apply to the input text

`Returns:` text_t

`*DIV` (double_at i)

Return the Double Value after dividing the current double value by the argument.

`Parameters``:`

i- Double

`Returns:` double_at

`*DIV` (ip_address_at i)

Return the Unsigned Long Value after dividing the current unsigned long value by the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*DIV` (unsigned_long_at i)

Return the Unsigned Long Value after dividing the current unsigned long value by the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*DIV` (num_at i)

Return the Number Value after dividing the current number value by the argument.

`Parameters``:`

i- Number

`Returns:` num_at

`*DIV` (time_local_at i)

Return the Unsigned Long Value after dividing the current unsigned long value by the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*DIV` (time_at i)

Return the Unsigned Long Value after dividing the current unsigned long value by the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*ENCRYPT`

Encrypt the selected plaintext bytes using the configured encryptionParams. The resulting ciphertext is base64-encoded.

`Returns:` text_t

`*ENCRYPT` (binary_encoding_e out_encoding)

Encrypt the selected plaintext bytes using the configured encryptionParams.

`Parameters` (expressions not allowed)`:`

out_encoding- specifies how the resulting ciphertext is encoded.

`Returns:` text_t

`*ENCRYPT` (text_t encryptionKey)

Encrypt the selected cleartext bytes using the configured encryption key.

`Parameters` (expressions not allowed)`:`

encryptionKey- identifies the encryptionKey object to provide the cipher method, mode, padding, key, encrypted format and optional initialization vector (IV).

`Returns:` text_t

`*ENCRYPT` (text_t encryptionKey, binary_encoding_e out_encoding)

Encrypt the selected cleartext bytes using the configured encryption key.

`Parameters` (expressions not allowed)`:`

encryptionKey- identifies the encryptionKey object to provide the cipher method, mode, padding, key, encrypted format and optional initialization vector (IV).

out_encoding- specifies how the resulting ciphertext is encoded.

`Returns:` text_t

`*ENDSWITH_ANY` (text_t patset_name)

Results in Boolean TRUE value if the Text ends with any of the strings that are bound to the patset or dataset named by the string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` bool_at

`*ENDSWITH_INDEX` (text_t patset_name)

Returns the numerical index of the matching string, if the Text ends with any of the strings that are bound to the patset or dataset named by the string argument. Returns 0 if there is no match. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` num_at

`*ENDSWITH` (text_t end)

Results in Boolean TRUE value if a suffix of the Text object matches the string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

end- String

`Returns:` bool_at

`*EQUALS_ANY` (text_t patset_name)

The EQUALS_ANY in this object overrides the Text EQUALS_ANY operator to operate on all the instances of the current header type. Returns Boolean TRUE if any of the patterns associated with input patset is equal to any instance of the header value. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Patset Name

`Returns:` bool_at

`*EQUALS_INDEX` (text_t patset_name)

The EQUALS_INDEX in this object overrides the Text EQUALS_INDEX operator to operate on all the instances of the current header type. Returns the index of the matching pattern associated with input patset is equal to any instance of the header value. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Patset Name

`Returns:` num_at

`*EQ` (double_at i)

Returns Boolean TRUE if the double value is equal to the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`*EQ` (ip_address_at i)

Returns Boolean TRUE if the unsigned long is equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*EQ` (unsigned_long_at i)

Returns Boolean TRUE if the unsigned long is equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*EQ` (num_at i)

Returns Boolean TRUE if the number value is equal to the argument.

`Parameters``:`

i- Number

`Returns:` bool_at

`*EQ` (text_t s)

Results in Boolean TRUE value if the Text object matches the input argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*EQ` (time_local_at i)

Returns Boolean TRUE if the unsigned long is equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*EQ` (time_at i)

Returns Boolean TRUE if the unsigned long is equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*EXISTS`

Returns TRUE if an instance of the current header type exists.

`Returns:` bool_at

`*GET_SIGNED16` (`uint` n, endian_e endianness)

Get the 16-bit signed binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

endianness- Select little or big endian

`Returns:` num_at

`*GET_SIGNED32` (`uint` n, endian_e endianness)

Get the 32-bit signed binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

endianness- Select little or big endian

`Returns:` num_at

`*GET_SIGNED8` (`uint` n)

Get the 8-bit signed binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

`Returns:` num_at

`*GET_UNSIGNED16` (`uint` n, endian_e endianness)

Get the 16-bit unsigned binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

endianness- Select little or big endian

`Returns:` num_at

`*GET_UNSIGNED32` (`uint` n, endian_e endianness)

Get the 32-bit unsigned binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

endianness- Select little or big endian

`Returns:` unsigned_long_at

`*GET_UNSIGNED64` (`uint` n, endian_e endianness)

Get the 64-bit unsigned binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

endianness- Select little or big endian

`Returns:` unsigned_long_at

`*GET_UNSIGNED8` (`uint` n)

Get the 8-bit unsigned binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

`Returns:` num_at

`*GET_URLSET_METADATA` (text_t urlset_name)

Returns metadata value corresponding to pattern in the urlset. The matching is case-insensitive for domains, but case-sensitive for paths. If no pattern is matched within the urlset, the return value is a NULL string. For example:

- HTTP.REQ.HOST.APPEND(HTTP.REQ.URL).GET_URLSET_METADATA("urlset_forbidden") returns value when the combined domain and URL is looked up in the urlset whose name is "urlset_forbidden".

`Parameters` (expressions not allowed) `:`

urlset_name- urlset name

`Returns:` text_t

`*GE` (double_at i)

Returns Boolean TRUE if the double value is greater than or equal to the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`*GE` (ip_address_at i)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*GE` (unsigned_long_at i)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*GE` (num_at i)

Returns Boolean TRUE if the number value is greater than or equal to the argument.

`Parameters``:`

i- Number

`Returns:` bool_at

`*GE` (text_t s)

Results in Boolean TRUE value if the Text object is greater than or equal to the input argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*GE` (time_local_at i)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*GE` (time_at i)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*GRPC`

Interprets a text_t string as a Protocol Buffer (protocol_buffer_t type). Example: HTTP.REQ.BODY(1000).GRPC.STRING(1).EQ("bookname")

`Returns:` protocol_buffer_t

`*GT` (double_at i)

Returns Boolean TRUE if the double value is greater than the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`*GT` (ip_address_at i)

Returns Boolean TRUE if the unsigned long value is greater than the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*GT` (unsigned_long_at i)

Returns Boolean TRUE if the unsigned long value is greater than the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*GT` (num_at i)

Returns Boolean TRUE if the number value is greater than the argument.

`Parameters``:`

i- Number

`Returns:` bool_at

`*GT` (text_t s)

Results in Boolean TRUE value if the Text object is greater than the input argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*GT` (time_local_at i)

Returns Boolean TRUE if the unsigned long value is greater than the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*GT` (time_at i)

Returns Boolean TRUE if the unsigned long value is greater than the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*HASH`

Returns a positive 31 bit integer value computed by applying a proprietary NetScaler hash function to the selected text. This function is not case- sensitive and ignores whitespaces. For example, applying the HASH function to two strings "Ab c" and "abc" would produce the same value. This function should not be used for security purposes; use instead the DIGEST function with one of the standard digest methods.

`Returns:` num_at

`*HMAC` (text_t hmacKey)

Returns a byte sequence computed by applying the HMAC (Hash Message Authenticastion Code) function to the selected text using the configured HMAC key.

`Parameters` (expressions not allowed) `:`

hmacKey- indentifies the hmacKey object to provide the digest (hash) method and the key.

`Returns:` text_t

`*HMAC` (text_t hmacKey, binary_encoding_e out_encoding)

Returns a byte sequence computed by applying the HMAC (Hash Message Authenticastion Code) function to the selected text using the configured HMAC key .

`Parameters` (expressions not allowed) `:`

hmacKey- indentifies the hmacKey object to provide the digest (hash) method and the key.

out_encoding- specifies how the resulting HMAC is encoded.

`Returns:` text_t

`*HTML_XML_SAFE`

Apply XML safe transform and select text.

Converts '<', '>' and '&' in the input text to '<', '>' and '&' respectively; other characters in the input are not modified. This transform safeguards against XSS based attacks. This is a read only operation.

`Returns:` text_t

`*HTTP_HEADER_SAFE`

Apply Header safe transform and select text. Converts all new line ('\\n') characters present in the input text to '%0A' so that they can safely be used in HTTP headers. This transform safeguards against response-splitting attacks. This is a read only operation.

`Returns:` text_t

`*HTTP_URL_SAFE`

Apply URL safe transform and select text. Converts URL unsafe characters to corresponding '%xx' values and retains the rest. This is a read only operation.

```
Based on RFC2396, following are considered URL safe characters:

    Alpha-numeric characters: a-z, A-Z, 0-9

    Hyphen and underscore: "-", "_"

    Dot: "."

    Exclamation mark: "!"

    Tilde: "~"

    Asterix: "&ast;"

    Single quote: "'"

    Open and close parentheses: "(", ")"

    Semi-colon: ";"

    Colon: ":"

    At symbol: "@"
```

```
    Question mark: "?"

    Equals: "="

    Dollar: "$"

    Percent: "%"

    Ampersand: "&"

    Plus: "+"

    Comma: ","

    Forward slash: ".html"
```

The rest are converted to %XX encoding, 'XX' is the hex-based representation of the input character. If the requirement is to encode all but URL unreserved characters, please consider using URL_RESERVED_CHARS_SAFE method.

`Returns:` text_t

`*INSTANCE` (`uint` lineno)

An HTTP header can have multiple occurrences. INSTANCE(0) will select the last header line of the current type, INSTANCE(1) will select the last but one header line and so on. The counting goes backward. Only the last 15 instances of a header are accessible. Therefore Instance Number cannot be greater than 14.

HTTP/1.1 200 OK\\r\\n MyHdr: abc\\r\\n Content-Length: 200\\r\\n MyHdr: def\\r\\n \\r\\n

For example: HTTP.RES.HEADER("MyHdr").INSTANCE(1) will return a Text object referring to "MyHdr: abc\\r\\n". It can not be used in HTTP response processing contexts.

`Parameters` (expressions not allowed) `:`

lineno- Instance Number

`Returns:` text_t

`*IS_BOOL_AT`

Results in Boolean TRUE value if the Text is of boolean type.

`Returns:` bool_at

`*IS_DOUBLE_AT`

Results in Boolean TRUE value if the Text is of double data type.

`Returns:` bool_at

`*IS_IPV6_AT`

Results in Boolean TRUE value if the Text is of IPv6 data type.

`Returns:` bool_at

`*IS_IPV6_SUBNET_AT`

Results in Boolean TRUE value if the Text is of IPv6 subnet data type.

`Returns:` bool_at

`*IS_IP_AT`

Results in Boolean TRUE value if the Text is of IPv4 data type.

`Returns:` bool_at

`*IS_MAC_ADDRESS_AT`

Results in Boolean TRUE value if the Text is of mac address data type.

`Returns:` bool_at

`*IS_NUM_AT`

Results in Boolean TRUE value if the Text is of number type.

`Returns:` bool_at

`*IS_NUM_AT` (num_format_e format)

Results in Boolean TRUE value if the Text is of number type with given input base.

`Parameters` (expressions not allowed) `:`

format- number format

`Returns:` bool_at

`*IS_STRINGMAP_KEY` (text_t string_map_name)

Returns true if the string that it operates on is present in the string map. Text mode IGNORECASE, NOIGNORECASE - controls whether key lookup in string map is case sensitive or not. For example:

- HTTP.REQ.URL.IS_STRINGMAP_KEY("url_stringmap") returns true if value of HTTP.REQ.URL is present as key in the string map whose name is "url_stringmap".
- HTTP.REQ.URL.SET_TEXT_MODE(IGNORECASE). IS_STRINGMAP_KEY("url_stringmap") returns true if value of HTTP.REQ.URL is present as key in the string map whose name is "url_stringmap". Key lookup in this case is done case-insensitively.

`Parameters` (expressions not allowed) `:`

string_map_name- identifies the string map.

`Returns:` bool_at

`*IS_TIME_AT`

Results in Boolean TRUE if the Text follows any of the standard time formats given below, otherwise false. Tue, 05 Nov 1994 08:12:31 GMT RFC822 Tuesday, 05-Nov-94 08:12:31 GMT RFC850 Tue Nov 4 08:12:31 1994 asctime

`Returns:` bool_at

`*IS_UNSIGNED_LONG_AT`

Results in Boolean TRUE value if the Text is of unsigned long data type.

`Returns:` bool_at

`*IS_UNSIGNED_LONG_AT` (num_format_e format)

Results in Boolean TRUE value if the Text is of unsigned long data type with given input base.

`Parameters` (expressions not allowed) `:`

format- number format

`Returns:` bool_at

`*JWT_VERIFY_CERTKEY` (text_t certkey_name)

Verifies the signature on the input JSON Web Token (JWT), using the RSA public key in the X.509 certificate in the specified certkey object. The token has the format HEADER.PAYLOAD.SIGNATURE where

- HEADER is a base64-encoded JSON structure indicating a signature algorithm and token type, e.g.'{"alg":"RS256","typ":"JWT"}'
- PAYLOAD is a base64-encoded JSON structure with asserted claims, e.g. '{"loggedInAs":"admin","iat":1422779638}'
- SIGNATURE is the base64-encoded bytes for the signature on HEADER.PAYLOAD.

Returns true if the signature is verified for the header and payload using the specified public key; false if the signature is not verified

`Parameters``:`

certkey_name- identifies the certkey object containing an X.509 certificate holding the RSA public key. Results in an Undef error if the certkey object does not exist or does not contain an X.509 certificate with an RSA public key, if the token is not correctly formatted, or if the verification operation cannot complete.

`Returns:` bool_at

`*JWT_VERIFY_XML` (text_t xml_pkey)

Verifies the signature on the input JSON Web Token (JWT), using the RSA public key supplied by the specified XML element. The token has the format HEADER.PAYLOAD.SIGNATURE where

- HEADER is a base64-encoded JSON structure indicating a signature algorithm and token type, e.g.'{"alg":"RS256","typ":"JWT"}'
- PAYLOAD is a base64-encoded JSON structure with asserted claims, e.g. '{"loggedInAs":"admin","iat":1422779638}'
- SIGNATURE is the base64-encoded bytes for the signature on HEADER.PAYLOAD.

Returns true if the signature is verified for the header and payload using the specified public key; false if the signature is not verified

`Parameters``:`

xml_pkey- an expression that supplies an <RSAKeyValue> element with the public key. Results in an Undef error if the XML element is invalid or does not correctly specify an RSA public key, if the token is not correctly formatted, or if the verification operation cannot complete.

`Returns:` bool_at

`*LENGTH`

Results in a Number Value that is the number of characters (not bytes) in the Text object.

`Returns:` num_at

`*LE` (double_at i)

Returns Boolean TRUE if the double value is lesser than or equal to the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`*LE` (ip_address_at i)

Returns Boolean TRUE if the unsigned long value is lesser than or equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*LE` (unsigned_long_at i)

Returns Boolean TRUE if the unsigned long value is lesser than or equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*LE` (num_at i)

Returns Boolean TRUE if the number value is lesser than or equal to the argument.

`Parameters``:`

i- Number

`Returns:` bool_at

`*LE` (text_t s)

Results in Boolean TRUE value if the Text object is less than or equal to the input argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*LE` (time_local_at i)

Returns Boolean TRUE if the unsigned long value is lesser than or equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*LE` (time_at i)

Returns Boolean TRUE if the unsigned long value is lesser than or equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*LOCATION_LONG`

Get the location qualifier from CLIENT.IP.SRC.LOCATION.GET(n) (ISO short name) and then convert it to human readable long name. This conversion is valid only for country names. Correct Country qualifier value (number) in GET(n) is left up to the user as qualifiers are user configurable. Expression example: CLIENT.IP.SRC.LOCATION.GET(1).LOCATION_LONG For example: Data from each expression CLIENT.IP.SRC.LOCATION: NA.US.California.SantaClara.*.* CLIENT.IP.SRC.LOCATION.GET(1): US CLIENT.IP.SRC.LOCATION.GET(1).LOCATION_LONG: United States

`Returns:` text_t

`*LSHIFT` (`uint` i)

Return the Number Value after bitwise left shifting the current number value by the argument number of bits. Note that the number of bits shifted is i modulo 32. For example, let HTTP.REQ.URL.LENGTH be 4. Then, HTTP.REQ.URL.LENGTH.LSHIFT(1) = HTTP.REQ.URL.LENGTH.LSHIFT(33) = 8, since 33 on division by 32 yields a remainder of 1.

`Parameters``:`

i- Left Shift Length

`Returns:` num_at

`*LT` (double_at i)

Returns Boolean TRUE if the double value is lesser than the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`*LT` (ip_address_at i)

Returns Boolean TRUE if the unsigned long value is lesser than the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*LT` (unsigned_long_at i)

Returns Boolean TRUE if the unsigned long value is lesser than the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*LT` (num_at i)

Returns Boolean TRUE if the number value is lesser than the argument.

`Parameters``:`

i- Number

`Returns:` bool_at

`*LT` (text_t s)

Results in Boolean TRUE value if the Text object is less than the input argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*LT` (time_local_at i)

Returns Boolean TRUE if the unsigned long value is lesser than the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*LT` (time_at i)

Returns Boolean TRUE if the unsigned long value is lesser than the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*MAP_STRING_DEFAULT_TO_KEY` (text_t string_map_name)

Returns the value corresponding to the key in the string map. This is similar to the MAP_STRING method, but if the key is not present then instead of returning a null string, it returns the key itself. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

string_map_name- identifies the string map.

`Returns:` text_t

`*MAP_STRING` (text_t string_map_name)

Returns value corresponding to key in the string map. Key is the string that it is given as input. Text mode IGNORECASE, NOIGNORECASE - controls whether key lookup in string map is case sensitive or not. For example:

- HTTP.REQ.URL.MAP_STRING("url_stringmap") returns value when the value of HTTP.REQ.URL is used as key in the string map whose name is "url_stringmap".
- HTTP.REQ.URL.SET_TEXT_MODE(IGNORECASE). MAP_STRING("url_stringmap") returns value when the value of HTTP.REQ.URL is used as key in the string map whose name is "url_stringmap". Key lookup in this case is done case-insensitively.

`Parameters` (expressions not allowed) `:`

string_map_name- identifies the string map.

`Returns:` text_t

`*MARK_SAFE`

Mark the PIXL expression safe without applying any safe transform.

`Returns:` text_t

`*MAX` (double_at i)

Return the maximum double value after comparing the argument with the current double value.

`Parameters``:`

i- Double

`Returns:` double_at

`*MAX` (ip_address_at i)

Return the maximum unsigned long value after comparing the argument value to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MAX` (unsigned_long_at i)

Return the maximum unsigned long value after comparing the argument value to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MAX` (num_at i)

Return the maximum value after comparing the argument with the current number value.

`Parameters``:`

i- Number

`Returns:` num_at

`*MAX` (text_t s)

Compares the string argument with the current string and returns the max string. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*MAX` (time_local_at i)

Return the maximum unsigned long value after comparing the argument value to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MAX` (time_at i)

Return the maximum unsigned long value after comparing the argument value to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MIN` (double_at i)

Return the minimum double value after comparing the argument with the current double value.

`Parameters``:`

i- Double

`Returns:` double_at

`*MIN` (ip_address_at i)

Return the minimum unsigned long value after comparing the argument value to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MIN` (unsigned_long_at i)

Return the minimum unsigned long value after comparing the argument value to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MIN` (num_at i)

Return the minimum value after comparing the argument with the current number value.

`Parameters``:`

i- Number

`Returns:` num_at

`*MIN` (text_t s)

Compares the string argument with the current string and returns the min string. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*MIN` (time_local_at i)

Return the minimum unsigned long value after comparing the argument value to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MIN` (time_at i)

Return the minimum unsigned long value after comparing the argument value to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MOD` (ip_address_at i)

Return the Unsigned Long Value that is the renaminder after dividing the current unsigned long value by the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MOD` (unsigned_long_at i)

Return the Unsigned Long Value that is the renaminder after dividing the current unsigned long value by the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MOD` (num_at i)

Return the Number Value that is the renaminder after dividing the current number value by the argument.

`Parameters``:`

i- Number

`Returns:` num_at

`*MOD` (time_local_at i)

Return the Unsigned Long Value that is the renaminder after dividing the current unsigned long value by the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MOD` (time_at i)

Return the Unsigned Long Value that is the renaminder after dividing the current unsigned long value by the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MUL` (double_at i)

Return the Double Value after multiplying the argument to the current double value.

`Parameters``:`

i- Double

`Returns:` double_at

`*MUL` (ip_address_at i)

Return the Unsigned Long Value after multiplying the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MUL` (unsigned_long_at i)

Return the Unsigned Long Value after multiplying the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MUL` (num_at i)

Return the Number Value after multiplying the argument to the current number value.

`Parameters``:`

i- Number

`Returns:` num_at

`*MUL` (time_local_at i)

Return the Unsigned Long Value after multiplying the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MUL` (time_at i)

Return the Unsigned Long Value after multiplying the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*NEG`

Return the Number Value after negating the current number value.

`Returns:` num_at

`*NE` (double_at i)

Returns Boolean TRUE if the double value is not equal to the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`*NE` (ip_address_at i)

Returns Boolean TRUE if the unsigned long value is not equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*NE` (unsigned_long_at i)

Returns Boolean TRUE if the unsigned long value is not equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*NE` (num_at i)

Returns Boolean TRUE if the number value is not equal to the argument.

`Parameters``:`

i- Number

`Returns:` bool_at

`*NE` (text_t s)

Results in Boolean TRUE value if the Text object is not equal to the input argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*NE` (time_local_at i)

Returns Boolean TRUE if the unsigned long value is not equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*NE` (time_at i)

Returns Boolean TRUE if the unsigned long value is not equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*NORMALIZE_URL`

Normalize URL. Normalizes a URL by doing "percent" decoding. See the description for URLENCODED in the SET_TEXT_MODE function. This performs the equivalent of

SET_TEXT_MODE(URLENCODED).DECODE_USING_TEXT_MODE, except that it does not change the value of the current text mode.

`Returns:` text_t

`*PKEY_ENCRYPT_PEM_NO_PADDING` (text_t pem_pkey)

Encrypts the input text using the RSA public key provided by the PEM string and RSA_NO_PADDING padding method. The input text to be encrypted cannot be longer than the public key length minus 11 bytes for padding. For example, for a 1024-bit (128 byte) key, the input text cannot be longer than 128 - 11 = 117 bytes. An Undef error will occur if the input text is too long. A null input will also cause an Undef error. Returns the (unencoded binary) encrypted text, which is typically base-64 encoded for use in a message.

`Parameters``:`

pem_pkey- a text expression that supplies a RSA public key in the PEM format. If the text value is not a valid PEM RSA PUBLIC KEY encoding, an Undef error will occur. Example (a 1024-bit public key):

```
"-----BEGIN RSA PUBLIC KEY-----" +

"MIGJAoGBAKl5vgQEj73Kxp+9yn1v5gPR1pnc4oLM2a0kaWwBOsB6rzCIy6znwnvw" +

"CY1xRvQhRlJSAyJbloL7wZFIJ2FOR8Cz+8ZQWXU2syG+udi4EnWqLgFYowF9zK+o" +

"79az597eNPAjsHZ/C2oL/+6qY5a/f1z8bQPrHC4GpFfAEJhh/+NnAgMBAAE=" +

"-----END RSA PUBLIC KEY-----"
```

`Returns:` text_t

`*PKEY_ENCRYPT_PEM` (text_t pem_pkey)

Encrypts the input text using the RSA public key provided by the PEM string and the RSA_PKCS1_PADDING padding method. The input text to be encrypted cannot be longer than the public key length minus 11 bytes for padding. For example, for a 1024-bit (128 byte) key, the input text cannot be longer than 128 - 11 = 117 bytes. An Undef error will occur if the input text is too long. A null input will also cause an Undef error. Returns the (unencoded binary) encrypted text, which is typically base-64 encoded for use in a message.

`Parameters``:`

pem_pkey- a text expression that supplies a RSA public key in the PEM format. If the text value is not a valid PEM RSA PUBLIC KEY encoding, an Undef error will occur. Example (a 1024-bit public key):

```
"-----BEGIN RSA PUBLIC KEY-----" +

"MIGJAoGBAKl5vgQEj73Kxp+9yn1v5gPR1pnc4oLM2a0kaWwBOsB6rzCIy6znwnvw" +

"CY1xRvQhRlJSAyJbloL7wZFIJ2FOR8Cz+8ZQWXU2syG+udi4EnWqLgFYowF9zK+o" +

"79az597eNPAjsHZ/C2oL/+6qY5a/f1z8bQPrHC4GpFfAEJhh/+NnAgMBAAE=" +

"-----END RSA PUBLIC KEY-----"
```

`Returns:` text_t

`*PKEY_SIGN_CERTKEY` (text_t certkey_name)

Generates a binary digital signature using the SHA-256 message digest function and an RSA private key from the specified SSL certKey object.

`Parameters``:`

certkey_name- identifies the configured certKey object. Results in an Undef error if the certkey object does not exist or does not contain an RSA private key, or if the signing operation cannot complete.

`Returns:` text_t

`*PKEY_SIGN_XML` (text_t xml_pkey)

Generates a binary digital signature using the SHA-256 message digest function and an RSA private key from the specified XML element.

`Parameters``:`

xml_pkey- an expression that supplies an <RSAKeyValue> element with the private key. Example: <RSAKeyValue> <Modulus>qXm+BASPvcrGn73KfW/
mA9HWmdzigszZrSRpbAE6wHqvMIjLrOfCe/
AJjXFG9CFGUlIDIluWgvvBkUgnYU5HwLP7xlBZdTazIb652LgSdaouAVijAX3Mr6jv1rPn3t408COwdn8Lagv/
7qpjlr9/XPxtA+scLgakV8AQmGH/42c=</Modulus> <Exponent>AQAB</Exponent>"zNjysxcIJV/
J9cTpIgPp2/x1IXHT5GTH8OMuNad0qtRSLjU1QYUmmkm9QcJJAN+7h8FEXWGabySUzBrHj/

IEbw==" <DP>QavUDQLLQpnPJXtVAo6CYhxOMCd68mwTxYKKNLjmC0pd54SFHllTLPE1FZU5EjK6q3nCeijonpfH+XX DP> <DQ>EiXOKouJzzXTQJC3TqomF7Uf81yQNxWumOqnd11kepXgyfMwyqMvLlAGEkNSEF/ Bz18R3Wv+MIZ/IC3nLBt2xQ==</DQ> <InverseQ>ocuCmz36CP+N2aGqxaU+BKD5+3RLgRq9LFhULEz2jKx0iV9r76jsAxn3sLcTYYO9eqRPy2cz74AU nw==</InverseQ> <D>fTBD773a3GzcmgVdfZlaBLpN1ux2mf5uUVrTUQf7eVFm9egm4/ tzC5A9zjC+I/oscwTH8epL3UfRLdtp05Q6pWfJBXEnGo0QmOFFBK4pLx/ 5JJpPGZ69ovDFEVOUHyiCfKE/g97T4WX3us0nFe1272zwGlHarM1YYwvfeE08UdE=</D> </ RSAKeyValue> Results in an Undef error if the XML element is invalid or does not correctly specify an RSA private key, or if the signing operation cannot complete.

`Returns:` text_t

`*PKEY_VERIFY_CERTKEY` (text_t certkey_name, text_t signature)

Verifies if the input text matches the specified signature generated using the SHA-256 messge digest function and the RSA private key associated with the specified RSA public key in the X.509 certificate in the specified certKey object. Returns true if the signature is verified, false otherwise.

`Parameters``:`

certkey_name- identifies the certkey object containing an X.509 certificate holding the RSA public key.

signature- the binary signature. Results in an Undef error if the certkey object does not exist or does not contain an X.509 certificate with an RSA public key, or if the verification operation cannot complete.

`Returns:` bool_at

`*PKEY_VERIFY_XML` (text_t xml_pkey, text_t signature)

Verifies if the input text matches the specified signature generated using the SHA-256 messge digest function and the RSA private key associated with the RSA public key supplied by the specified XML element. Returns true if the signature is verified, false otherwise.

`Parameters``:`

xml_pkey- an expression that supplies an <RSAKeyVAlue> element with the public key. Example: <RSAKeyValue> <Modulus>qXm+BASPvcrGn73KfW/ mA9HWmdzigszZrSRpbAE6wHqvMIjLrOfCe/ AJjXFG9CFGUlIDIluWgvvBkUgnYU5HwLP7xlBZdTazIb652LgSdaouAVijAX3Mr6jv1rPn3t408COwdn8Lagv/

7qpjlr9/XPxtA+scLgakV8AQmGH/42c=</Modulus> <Exponent>AQAB</Exponent> </RSAKeyValue>

signature- the binary signature. Results in an Undef error if the XML element is invalid or does not correctly specify an RSA public key, or if the verification operation cannot complete.

`Returns:` bool_at

`*PREFIX` (`char` c, `uint` i)

Select a prefix of the Text. The selected prefix is the longest prefix that has at most Count (2nd argument) occurrences of character in the 1st argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

c- Character

i- Count

`Returns:` text_t

`*PREFIX` (`uint` i)

Select a prefix of the Text. The length of the prefix is equal to the number in the argument. If there aren't enough characters in the Text object then the entire Text is selected.

`Parameters``:`

i- Prefix Length

`Returns:` text_t

`*REGEX_MATCH` (`re` regex)

The REGEX_MATCH operator in this object overrides the Text REGEX_MATCH operator to operate on all the instances of the current header type. Returns Boolean TRUE if the input regular expression matches any instance of the header value. The order in which the header instances will be matched is from the last to the first.

The regular expression has to be of the format: `re<delimiter>regular expression<same delimiter>`

The regular expression cannot be bigger than 1499 characters.

The regular expression should be acceptable by the PCRE regular expression library. Look at http://www.pcre.org/pcre.txt for documentation on the regular expression syntax. In particular, look at the pcrepattern man page.

There are some differences in the allowed syntax w.r.t PCRE syntax. Backreferences are not allowed. It is recommended to not use recursive regular expressions. The dot metacharacter matches newlines also. Unicode is not supported. SET_TEXT_MODE(IGNORECASE) overrides the (?i) internal option specified in the regular expression.

The PCRE library configuration can be seen in the system log, after executing 'nsapimgr -B" call ns_pixl_regex_show_config()"' at the shell prompt.

Some examples:

- HTTP.REQ.HOSTNAME.REGEX_MATCH(re/\[\[:alpha:\]\]+(abc){2,3}/)
- HTTP.REQ.URL.SET_TEXT_MODE(URLENCODED).REGEX_MATCH(re#(a*b+c*)#)
- HTTP.REQ.URL.REGEX_MATCH(re/a(?i)b/) matches ab and aB
- HTTP.REQ.URL.SET_TEXT_MODE(IGNORECASE).REGEX_MATCH(re/ab/) matches ab, aB, Ab and AB
- HTTP.REQ.BODY.REGEX_MATCH(re/(?ixm) (\^ab (.*) cd$) /) does a case-insensitive, multiline match where the dot metacharacter matches newline also. The regex itself can contain whitespace which will be ignored during the matching (x - extended regex).

This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

regex- Regular Expression

`Returns:` bool_at

`*REGEX_REPLACE` (`re` regex, text_t replacement, replacemode_e mode)

Selects the text that matches the given regular expression argument and replaces it with the the text given in the second argument. The third argument specifies whether the first match is only replaced when multiple matches occur in the text or all matches are replaced. The match may occur anywhere within the text - if you wish to "anchor" this, use "\^" at the start of the regex and/or "$" at the end of the regex. When the regular expression does not match the given string then the same string is returned.

For example: HTTP.RES.BODY(999).REGEX_REPLACE(re!\\bpassword:\\s*\\b!, "password: ***", ALL) will replace all occurrences of "password:" with "password: ***" This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

regex- Regular Expression

replacement- String to replace the match

mode- Mode of replacement

`Returns:` text_t

`*REGEX_SELECT` (`re` regex)

The REGEX_SELECT operator in this object overrides the Text REGEX_SELECT operator to operate on all the instances of the current header type. Selects the Text that matches the input regular expression in any instance of the header value. The order in which the header instances will be matched is from the last to the first.

For example: HTTP.REQ.HEADER("via").REGEX_SELECT(re!NS-CACHE-\\d\\.\\d:\\s*\\d{1,3}!) will select "NS-CACHE-7.0: 70" This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

regex- Regular Expression

`Returns:` text_t

`*REPEAT` (`uint` i)

Produces a string which contains 'i' sequential copies of the input string.

`Parameters``:`

i- the number of times to repeat the string (0 or more)

`Returns:` text_t

`*RSHIFT` (`uint` i)

Return the Number Value after bitwise right shifting the current number value by the argument number of bits. Note that the number of bits shifted is i modulo 32. For example, let HTTP.REQ.URL.LENGTH be 4. Then, HTTP.REQ.URL.LENGTH.RSHIFT(1) = HTTP.REQ.URL.LENGTH.RSHIFT(33) = 2, since 33 on division by 32 yields a remainder of 1.

`Parameters``:`

i- Right Shift Length

`Returns:` num_at

`*SET_CHAR_SET` (charset_e charset)

Set the character set to use for subsequent functions that use text.

`Parameters` (expressions not allowed) `:`

charset- Character Set

`Returns:` http_content_length_t

`*SET_TEXT_MODE` (textmode_e mode)

The mode setting of a Text object controls the behavior of many Text operations. The Text mode settings may also control the behavior of some operations in objects (like List) that build upon the Text object. IGNORECASE, NOIGNORECASE - controls whether string comparison is case sensitive or not. URLENCODED - If set then all Text operations are carried out after translating all %HH or %uHHHH encodings in the underlying byte stream. 1. %HH will be translated to the character Y where HH denotes the ascii value of character Y in hexadecimal. For example, the encoded text "http%3a/.html" will be decoded to "http:/.html" 2. %uWWHH will be translated to the character sequence YZ where WW denotes the ascii value of character Y in hexadecimal and HH denotes the ascii value of character Z in hexadecimal. For example, the encoded text "http%u3a2f.html" and "http%u003a/.html" will both be decoded to"http:/.html" NOURLENCODED - Indicates that no percent encodings are present in the Text object. No percent decoding will be performed on the Text object. PLUS_AS_SPACE - If set then all Text operations are carried out after converting occurrences of the plus character to whitespace. For example, the text "hello+world" will be decoded to "hello world" NO_PLUS_AS_SPACE - If set, then the plus character will not be converted to whitespace in the Text object. BACKSLASH_ENCODED - If set, then all Text operations are carried out after performing the following operations: 1. \\XXX will be translated to the character Y where XXX denotes the ascii value of character Y in octal. The valid range of octal values for this type of encoding is \\0 to \\377. For example, the encoded text "http\

\72/.html" and "http\\072/.html" will both be decoded to "http:/.html" 2. \\xHH will be translated to the character Y where HH denotes the ascii value of character Y in hexadecimal. For example, the encoded text "http\\x3a/.html" will be decoded to "http:/.html" 3. \\\\uWWXX will be translated to the character sequence YZ where WW denotes the ascii value of character Y in hexadecimal and XX denotes the ascii value of character Z in hexadecimal. For example, the encoded text "http%u3a2f.html" and "http%u003a/.html" will both be decoded to"http:/.html" 4. Occurences of "\ \b", "\\n", "\\t", "\\f" and "\\r" are translated to the corresponding ascii characters. NO_BACKSLASH_ENCODED - If set, then backslash decoding will not be performed on the Text object. BAD_ENCODE_RAISE_UNDEF - If set, then UNDEF is raised if either the URLENCODED or BACKSLASH_ENCODED mode is set and a bad encoding corresponding to the specified encoding mode is encountered. NO_BAD_ENCODE_RAISE_UNDEF - If set, then UNDEF will not be raised when a bad encoding is encountered in the Text object. The Text operations operate on characters (as opposed to operating on bytes). By default a single byte represents a character using the ASCII encoding. But if URLENCODED mode is set then 3 bytes may represent a character. A PREFIX(3) operation will select the first 3 characters in the Text object. That means it may select up to 9 bytes for URLENCODED Text object. In the case of multibyte decodings as a result of %uXXXX or \\\\uXXXX, Text operations which attempt to treat the multiple decoded bytes as distinct characters are not allowed.

`Parameters` (expressions not allowed) `:`

mode- Text Mode

`Returns:` http_content_length_t

`*SIGNED16_STRING` (endian_e endianness)

Create a signed 16-bit binary string from the number.

`Parameters` (expressions not allowed) `:`

endianness- Select little or big endian

`Returns:` text_t

`*SIGNED32_STRING` (endian_e endianness)

Create a signed 32-bit binary string from the number.

`Parameters` (expressions not allowed) `:`

endianness- Select little or big endian

`Returns:` text_t

`*SIGNED8_STRING`

Create a signed 8-bit binary string from the number.

`Returns:` text_t

`*SKIP` (`char` c, `uint` i)

Select the Text after skipping over a prefix of the current Text. The skipped over prefix is the longest prefix that has at most Count (2nd argument) occurrences of character in the 1st argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

c- Character

i- Count

`Returns:` text_t

`*SKIP` (`uint` i)

Select the Text after skipping over a prefix in the current Text. The length of the prefix is equal to the number in the argument. If there aren't enough characters in the Text object then the entire Text is skipped over.

`Parameters` (expressions not allowed) `:`

i- Prefix Length

`Returns:` text_t

`*STARTSWITH_ANY` (text_t patset_name)

Results in Boolean TRUE value if the Text starts with any of the strings that are bound to the patset or dataset named by the string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` bool_at

`*STARTSWITH_INDEX` (text_t patset_name)

Returns the numerical index of the matching string, if the Text starts with any of the strings that are bound to the patset or dataset named by the string argument. Returns 0 if there is no match. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` num_at

`*STARTSWITH` (text_t start)

Results in Boolean TRUE value if a prefix of the Text object matches the string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

start- String

`Returns:` bool_at

`*STRIP_CHARS` (text_t s)

From the selected text remove the characters specified in the string.

For example: Say the selected text is / "foo.xyz=bar" /. Then on executing STRIP_CHARS('.=') or STRIP_CHARS('..=') the selected text will become /fooxyzbar /. Note that repeating character has same effect as it would be if it present only once. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*STRIP_END_CHARS` (text_t s)

Selects the Text after stripping off characters in the end of the current Text object.

For example: Say the selected text is / "foo.xyz=bar" /. Then on executing STRIP_END_CHARS('ar') the selected text will become /foo.xyz=b /. Note that repeating character

has same effect as it would be if it present only once. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*STRIP_END_WS`

Selects the Text after stripping off white space in the end of the current Text object.

`Returns:` text_t

`*STRIP_START_CHARS` (text_t s)

Selects the Text after stripping off characters in the beginning of the current Text object.

For example: Say the selected text is / "foo.xyz=bar" /. Then on executing STRIP_START_CHARS('of') the selected text will become /.xyz=bar /. Note that repeating character has same effect as it would be if it present only once. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*STRIP_START_WS`

Selects the Text after stripping off white space in the beginning of the current Text object.

`Returns:` text_t

`*SUBSTR_ANY` (text_t patset_name)

Select any one sub-string that matches any string in the given patset or dataset. The patset cannot have strings longer than 255 characters. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed)`:`

patset_name- Pattern Set Name

`Returns:` text_t

`*SUBSTR` (`uint` start, `uint` len)

Select the Text object of the given length at the given offset. Offset it 0 based. If there aren't enough characters after the offset then all the remaining characters are selected.

`Parameters``:`

start- Offset

len- Length

`Returns:` text_t

`*SUBSTR` (text_t s)

The SUBSTR operator in this object overrides the Text SUBSTR operator to operate on all the instances of the current header type. Selects Text that matches the input string argument. The order in which the instances of the header are matched is from the last instance to the first.

HTTP/1.1 200 OK\\r\\n MyHdr: 111abc\\r\\n Content-Length: 200\\r\\n MyHdr: 111def\\r\\n \\r\\n

For example: HTTP.RES.HEADER("MyHdr").SUBSTR("111") selects "111" in the last instance of MyHdr, the one with value "111def". This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*SUB` (double_at i)

Return the Double Value after subtracting the argument from the current double value.

`Parameters``:`

i- Double

`Returns:` double_at

`*SUB` (ip_address_at i)

Return the Unsigned Long Value after subtracting the argument from the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*SUB` (unsigned_long_at i)

Return the Unsigned Long Value after subtracting the argument from the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*SUB` (num_at i)

Return the Number Value after subtracting the argument from the current number value.

`Parameters``:`

i- Number

`Returns:` num_at

`*SUB` (time_local_at i)

Return the Unsigned Long Value after subtracting the argument from the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*SUB` (time_at i)

Return the Unsigned Long Value after subtracting the argument from the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*SUFFIX` (`char` c, `uint` i)

Select a suffix of the Text. The selected suffix is the longest possible suffix containing at most Count (2nd arg) occurrences of the character in the 1st argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

c- Character

i- Count

`Returns:` text_t

`*SUFFIX` (`uint` i)

Select a suffix of the Text. The length of the suffix is equal to the number in the argument. If there aren't enough characters in the Text object then the entire Text is selected.

`Parameters``:`

i- Suffix Length

`Returns:` text_t

`*TO_LOWER`

Converts the selected text to lower case.

For example, the string "ABCd" is converted to "abcd"

`Returns:` text_t

`*TO_UPPER`

Converts the selected text to upper case.

For example, the string "abcD" is converted to "ABCD"

`Returns:` text_t

`*TRUNCATE` (`char` c, `uint` i)

Select the Text after truncating a suffix from the current Text object. The truncated suffix is the longest possible suffix containing at most Count (2nd arg) occurrences of the character in the 1st argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

c- Character

i- Count

`Returns:` text_t

`*TRUNCATE` (`uint` i)

Select the Text after truncating a suffix of the Text. The length of the suffix truncated is equal to the number in the argument. If there aren't enough characters in the Text then then all the characters are truncated.

`Parameters``:`

i- Suffix Length

`Returns:` text_t

`*TYPECAST_AVP_T`

Convert text_t to avp_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (avp_t : Operations that can be performed on the returned AVPs.

`Note:` An AVP can have multiple instances in a Diameter message. However, the system can access only the first 16 instances.

`Example:`

- To get the first value of AVP code 266 from a request, use: DIAMETER.REQ.AVP(266).VALUE(0).
- To get the fourth value of AVP code 266 from a request, use: DIAMETER.REQ.AVP(266).VALUE(3).
- To check if AVP code 1000 in the response has the vendor-specific bit set, use: DIAMETER.RES.AVP(1000).IS_VENDOR_SPECIFIC.

)

`Returns:` avp_t

`*TYPECAST_AVP_UNUM_T`

Convert text_t to avp_unum_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (avp_unum_t : In Diameter AVP based expressions can be written as DIAMETER.REQ.AVP(<avpcode>). For example Auth-Application-Id AVP (AVP code 258) can be extracted as DIAMETER.REQ.AVP(258) For few of the important AVPs we provide aliases. For example this AVP based expression can also be written as DIAMETER.REQ.AUTH_APPLICATION_ID. This expression returns either a object of class avp_t or returns a numerical value (object of class unsigned_long_at). The numerical value for this object is derived from the value in first instance of the AVP.)

`Returns:` avp_unum_t

`*TYPECAST_BOOL_AT`

Convert text_t to bool_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (bool_at : Boolean Operations)

`Returns:` bool_at

`*TYPECAST_COOKIE_T`

Convert text_t to cookie_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (cookie_t : The HTTP Cookie type provides operations for a cookie as it appears in the Set-Cookie and Set-Cookie2 header. In this type the Name-Value List operations are also available. The first delimiter is = and the element delimiter is ;. Multiple consecutive ; are treated as one. (Same as applying the method IGNORE_EMPTY_ELEMENTS on a Name-Value List.) You can use the Name-value List operations to access cookie attributes. The name comparison for all list operations is case insensitive. In this type Text operations are also available. Each cookie begins with a COOKIE_NAME=COOKIE_VALUE pair followed by zero or more semi-colon separated attribute-value pairs. If an attribute appears more than once in a cookie, the value associated with the first appearance of the attribute is returned.

Format Cookie: Cookie1=Value;Version=decimal;Value;Domain=Value;Path=Value)

`Returns:` cookie_t

`*TYPECAST_DIAMETER_FLAG_T`

Convert text_t to diameter_flag_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (diameter_flag_t : Provides operation to treat the underlying 1 byte as set of bit flags. then set/unset/test/reset_all operations can be done on flag)

`Returns:` diameter_flag_t

`*TYPECAST_DNS_DOMAINNAME_T`

Convert text_t to dns_domainname_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (dns_domainname_t : This object provides operations for parsing the DNS domain name as it appears at various places in the DNS data. The format is abc.foo.com.)

`Returns:` dns_domainname_t

`*TYPECAST_DNS_FLAG_T`

Convert text_t to dns_flag_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (dns_flag_t : Provides operations to test/set/unset a flag in dns header.)

`Returns:` dns_flag_t

`*TYPECAST_DOUBLE_AT`

Typecast the Number Value to a Double value.

`Returns:` double_at

`*TYPECAST_DOUBLE_T` (double_format_e format)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error.)

`Parameters` (expressions not allowed) `:`

format- Format

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, double_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, ip_address_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, num_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one

or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, time_local_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, time_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, unsigned_long_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_HTTP_CACHE_CONTROL_T`

Convert text_t to http_cache_control_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_cache_control_t : This object provides for the ability to work on HTTP Cache-Control headers. The name comparison for all list operations is case insensitive.)

`Returns:` http_cache_control_t

`*TYPECAST_HTTP_CONTENT_LENGTH_T`

Convert text_t to http_content_length_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_content_length_t : The HTTP.REQ.CONTENT_LENGTH or HTTP.RES.CONTENT_LENGTH object can be treated as a HTTP Header or as a Number. The numerical value for this object is derived from the value in the last instance of the Content-Length header.)

`Returns:` http_content_length_t

`*TYPECAST_HTTP_COOKIE_T`

Convert text_t to http_cookie_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_cookie_t : This object provides operations for parsing

the HTTP cookie header. The name-value pair is derived from the value in the last instance of Cookie header. The format is Cookie : name0=value0; name1=value1; An HTTP Cookie header can have multiple occurrences. COUNT will return a Number containing how many headers of the current type exist. The name comparison for all list operations is case insensitive. The system does not keep track of more than 15 HTTP headers. The result will be undefined if there are more than 15 instances of the header.)

`Returns:` http_cookie_t

`*TYPECAST_HTTP_DATE_T`

Convert text_t to http_date_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_date_t : The HTTP.REQ.DATE or HTTP.RES.DATE object can be treated as a HTTP header or a Time object. The Time value is derived from the value in the last instance of the Date header. The date formats supported are RFC 822 (updated by RFC 1123), RFC 1036 (obsoletes RFC850) and ANSI C asctime() formats.)

`Returns:` http_date_t

`*TYPECAST_HTTP_HEADER_T` (text_t name)

Convert text_t to http_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_header_t : When typecasting a Text object to HTTP Header a header name must be provided.For example: HTTP.REQ.HEADER("MyHdr").TYPECAST_HTTP_HEADER_T("InHdr"))

`Parameters` (expressions not allowed) `:`

name- Header Name

`Returns:` http_header_t

`*TYPECAST_HTTP_HOSTNAME_T`

Convert text_t to http_hostname_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_hostname_t : This object provides operations for parsing the HTTP hostname as it appears at various places in the HTTP protocol data. The format is abc.foo.com:8080.)

`Returns:` http_hostname_t

`*TYPECAST_HTTP_METHOD_T`

Convert text_t to http_method_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_method_t : This object provides Text operations and HTTP Request Method Enum operations on the HTTP request method.)

`Returns:` http_method_t

`*TYPECAST_HTTP_SET_COOKIE_T`

Convert text_t to http_set_cookie_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_set_cookie_t : HTTP.RES.SET_COOKIE provides operations for parsing and operating on the SET-COOKIE header that is present in the HTTP response. HTTP Set-Cookie header supports Text and HTTP Header operations. For most Text operations the value in the last Set-Cookie header is selected. HTTP Set-Cookie header also supports special operations to extract cookies from the response. It is assumed that there will be only one cookie in a Set-Cookie header.)

`Returns:` http_set_cookie_t

`*TYPECAST_HTTP_URL_T`

Convert text_t to http_url_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_url_t : HTTP.REQ.URL provides operations for parsing and operating on the URL that is present in the first line of the HTTP request header. The supported format is \[<protocol>://<hostname>\]<path>?<query>. The Text object backing a HTTP URL object has the Text Mode set to URLENCODED by default.)

`Returns:` http_url_t

`*TYPECAST_HTTP_VERSION_T`

Convert text_t to http_version_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_version_t : HTTP.REQ.VERSION or HTTP.RES.VERSION provide operations to extract HTTP version information.)

`Returns:` http_version_t

`*TYPECAST_IPV6_ADDRESS_AT`

Convert text_t to ipv6_address_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ipv6_address_at : Provides operations for the 128-bit IPv6 address value. Some general information regarding IPv6 expressions: IPv6 PIXL expressions can be combined with other PIXL expressions using the '+' operator. The output is expected to be

the concatenation of the string representations of the individual PIXL expressions. No other operator other than '+' is expected to work when any of the operands is an IPv6 PIXL expression. Also, IPv6 PIXL expressions can be combined with any other type of PIXL expression except a PIXL expression that produces a bool result. In other words, if A and/or B are two IPv6 addresses, A+B should result in the string AB. When one of A or B is an IPv6 address, the other can only be a number or a string and not a boolean. Further, when A and/or B is an IPv6 address, the only operator allowed between them is '+'.

Example: Let the client source IPv6 address be ABCD:1234::ABCD. Let the server destination IPv4 address be 10.100.10.100. Then the expression CLIENT.IPV6.SRC + SERVER.IP.DST should produce the output "ABCD:1234::ABCD10.100.10.100". Similarly, CLIENT.IPV6.SRC + 5 should produce the result ABCD:1234::ABCD5)

`Returns:` ipv6_address_at

`*TYPECAST_IPV6_ADDRESS_T`

Convert text_t to ipv6_address_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ipv6_address_t : This object represents an IPv6 address present in the 1000:1001:CD10:0000:0000:89AB:4567:CDEF format.)

`Returns:` ipv6_address_t

`*TYPECAST_IPV6_SUBNET_AT`

Convert text_t to ipv6_subnet_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ipv6_subnet_at : Provides operations for the integral IPv6 subnet address value.)

`Returns:` ipv6_subnet_at

`*TYPECAST_IPV6_SUBNET_T`

Convert text_t to ipv6_subnet_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ipv6_subnet_t : This object represents an IPv6 subnet address present in the 1000:1001:CD10:0000:0000:89AB:4567:CDEF/64 format.)

`Returns:` ipv6_subnet_t

`*TYPECAST_IP_ADDRESS_AT`

Typecast the Number Value to an IP Address value.

`Returns:` ip_address_at

`*TYPECAST_IP_ADDRESS_T`

Convert text_t to ip_address_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ip_address_t : Represents an IP address present in the 10.100.200.1 format.)

`Returns:` ip_address_t

`*TYPECAST_IP_OPTIONS_T`

Convert text_t to ip_options_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ip_options_t : IP protocol options)

`Returns:` ip_options_t

`*TYPECAST_IP_OPTIONS_TYPE_T`

Convert text_t to ip_options_type_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ip_options_type_t : IP Options Type)

`Returns:` ip_options_type_t

`*TYPECAST_IP_TOS_T`

Convert text_t to ip_tos_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ip_tos_t : Provides operations to TOS field in IP header.)

`Returns:` ip_tos_t

`*TYPECAST_LIST_T` (`char` sep)

Convert text_t to list_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (list_t : The character separator has to be provided when typecasting a textual context to list type. The current text mode has no effect on the character separator. For example if the current text mode is IGNORECASE and the separator is p then P will not be treated as a separator.)

`Parameters` (expressions not allowed) `:`

sep- Separator

`Returns:` list_t

`*TYPECAST_MAC_ADDRESS_AT`

Convert text_t to mac_address_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (mac_address_at : Provides operations for the 48-bit MAC address value.)

`Returns:` mac_address_at

`*TYPECAST_MAC_ADDRESS_T`

Convert text_t to mac_address_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (mac_address_t : Represents a MAC address present in the 12:34:56:78:9a:bc format.)

`Returns:` mac_address_t

`*TYPECAST_NUM_T` (num_format_e format)

Convert text_t to num_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (num_t : Treat the underlying text as a Number in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error.)

`Parameters` (expressions not allowed) `:`

format- Format

`Returns:` num_t

`*TYPECAST_NUM_T` (num_format_e format, num_at default_value)

Convert text_t to num_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (num_t : Treat the underlying text as a Number in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` num_t

`*TYPECAST_NVLIST_T` (`char` sep1, `char` sep2)

Convert text_t to nvlist_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (nvlist_t : Two character delimiters have to be provided when typecasting a Text object to a Name-Value List. The first delimited separates the name from the value. The second delimiter separates list items. For example typecast_nvlist_t('=', '&') handles a URL query string. The Text Mode has no effect on the character delimiters. For example if the current text mode is IGNORECASE and a delimiter is p then P will not be treated as a delimiter.)

`Parameters` (expressions not allowed) `:`

sep1- delimiter1

sep2- delimiter2

`Returns:` nvlist_t

`*TYPECAST_NVLIST_T` (`char` sep1, `char` sep2, `char` quote)

Convert text_t to nvlist_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (nvlist_t : Two character delimiters and quote-character have to be provided when typecasting a Text object to a Name-Value List that supports quote-character. The first delimited separates the name from the value. The second delimiter separates list items. The third value specifies the quote character. For example typecast_nvlist_t('=', ';', "") handles a name-value list separated by semi-colons that allows quoting. The quote-character specifies that the value can occur within the quotes and the delimiters within the quote-characters should not be taken into account. The Text Mode has no effect on the character delimiters. For example if the current text mode is IGNORECASE and a delimiter is p then P will not be treated as a delimiter.)

`Parameters` (expressions not allowed) `:`

sep1- delimiter1

sep2- delimiter2

quote- quote-character.

`Returns:` nvlist_t

`*TYPECAST_PROTOCOL_BUFFER_T`

Convert text_t to protocol_buffer_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (protocol_buffer_t : gRPC Protocol Buffers interface)

`Returns:` protocol_buffer_t

`*TYPECAST_RADIUS_AVP_T`

Convert text_t to radius_avp_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (radius_avp_t : Operations that can be performed on the returned AVPs.

`Note:` An AVP can have multiple instances in a radius message. However, the system can access only the first 16 instances.

`Example:`

- To get the first value of AVP code 26 from a request, use: radius.REQ.AVP(26).VALUE(0).
- To get the fourth value of AVP code 26 from a request, use: radius.REQ.AVP(26).VALUE(3).

)

`Returns:` radius_avp_t

`*TYPECAST_RADIUS_AVP_VALUE_T`

Convert text_t to radius_avp_value_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (radius_avp_value_t : Provides operations to typecast RADIUS AVP value to Integer value or IP Address.)

`Returns:` radius_avp_value_t

`*TYPECAST_SEQ_TEXT_T`

Convert text_t to seq_text_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (seq_text_t : Represents the Text Sequence class.)

`Returns:` seq_text_t

`*TYPECAST_SERVICEPATH_T`

Convert text_t to servicepath_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (servicepath_t : Operations that can be performed on the service path.

`Example:`

- To get the name of the service path applicable to current subscriber, use: SUBSCRIBER.SERVICEPATH
- To determine If the service function is the next in the service path applicable to scubscriber, use: SUBSCRIBER.SERVICEPATH.IS_NEXT().

)

`Returns:` servicepath_t

`*TYPECAST_SIP_CALLID_HEADER_T`

Convert text_t to sip_callid_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_callid_header_t : This object provides operations for parsing the SIP callid header.)

`Returns:` sip_callid_header_t

`*TYPECAST_SIP_CONTENT_LENGTH_T`

Convert text_t to sip_content_length_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_content_length_t : The SIP.REQ.CONTENT_LENGTH or SIP.RES.CONTENT_LENGTH object can be treated as a SIP Header or as a Number. The numerical value for this object is derived from the value in the last instance of the Content-Length header.)

`Returns:` sip_content_length_t

`*TYPECAST_SIP_FROM_HEADER_T`

Convert text_t to sip_from_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_from_header_t : This object provides operations for parsing the SIP From header.)

`Returns:` sip_from_header_t

`*TYPECAST_SIP_HEADER_T` (text_t name)

Convert text_t to sip_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_header_t : When typecasting a Text object to SIP Header a header name must be provided.For example: SIP.REQ.HEADER("MyHdr").TYPECAST_SIP_HEADER_T("InHdr"))

`Parameters` (expressions not allowed) `:`

name- Header Name

`Returns:` sip_header_t

`*TYPECAST_SIP_HOSTNAME_T`

Convert text_t to sip_hostname_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_hostname_t : This object provides operations for parsing the SIP hostname as it appears at various places in the SIP protocol data. The format is abc.foo.com:5060.)

`Returns:` sip_hostname_t

`*TYPECAST_SIP_METHOD_T`

Convert text_t to sip_method_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_method_t : This object provides Text operations and SIP Request Method Enum operations on the SIP request method.)

`Returns:` sip_method_t

`*TYPECAST_SIP_TO_HEADER_T`

Convert text_t to sip_to_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_to_header_t : This object provides operations for parsing the SIP From header.)

`Returns:` sip_to_header_t

`*TYPECAST_SIP_URL_T`

Convert text_t to sip_url_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_url_t : SIP.REQ.URL provides operations for parsing and operating on the URL that is present in the first line of the SIP request header. The supported format is \[<protocol>://<hostname>\]<path>?<query>. The Text object backing a SIP URL object has the Text Mode set to URLENCODED by default.)

`Returns:` sip_url_t

`*TYPECAST_SIP_VERSION_T`

Convert text_t to sip_version_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_version_t : SIP.REQ.VERSION or SIP.RES.VERSION provide operations to extract SIP version information.)

`Returns:` sip_version_t

`*TYPECAST_SIP_VIA_HEADER_T`

Convert text_t to sip_via_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_via_header_t : This object provides operations for parsing the SIP Via header.)

`Returns:` sip_via_header_t

`*TYPECAST_SSLVPN_MODE_T`

Convert text_t to sslvpn_mode_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sslvpn_mode_t : This object provides Text operations and SSLVPN Mode Enum operations on the SSLVPN request method.)

`Returns:` sslvpn_mode_t

`*TYPECAST_SSL_TEXT_T` (text_t name)

Convert text_t to ssl_text_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ssl_text_t : Treat the underlying text object as SSL Text.)

`Parameters` (expressions not allowed) `:`

name- Name

`Returns:` ssl_text_t

`*TYPECAST_TCP_OPTIONS_T`

Convert text_t to tcp_options_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (tcp_options_t : TCP Protocol Options)

`Returns:` tcp_options_t

`*TYPECAST_TCP_OPTIONS_TYPE_T`

Convert text_t to tcp_options_type_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (tcp_options_type_t : TCP Protocol Options Type)

`Returns:` tcp_options_type_t

`*TYPECAST_TCP_REPEATER_OPTION_T`

Convert text_t to tcp_repeater_option_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (tcp_repeater_option_t : TCP Protocol Option : Repeater)

`Returns:` tcp_repeater_option_t

`*TYPECAST_TEXT_T`

Typecast the Number Value to its string representation.

`Returns:` text_t

`*TYPECAST_TIME_AT`

Typecast the Number Value to a Time value.

`Returns:` time_at

`*TYPECAST_TIME_LOCAL_AT`

Typecast the Number Value to a local time value.

`Returns:` time_local_at

`*TYPECAST_TIME_T`

Convert text_t to time_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (time_t : This object treats a Text object as a date string. The formats supported are

1\. RFC822 :: Sun, 06 Nov 1994 08:49:37 GMT 2\. RFC850 :: Sunday, 06-Nov-94 08:49:37 GMT 3\. ASCTIME :: Sun Nov 6 08:49:37 1994 4\. ASCTIME like :: Sun Nov 6 08:49:37 1994 5\. ASCTIME like :: Sun Nov 06 08:49:37 1994 6\. Http Set-Cookie Expiry date :: Sun, 06-Nov-1994 08:49:37 GMT)

`Returns:` time_t

`*TYPECAST_UNSIGNED_LONG_AT`

Typecast the Number Value to a Unsigned Long value.

`Returns:` unsigned_long_at

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error.)

`Parameters` (expressions not allowed) `:`

format- Format

`Returns:` unsigned_long_t

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format, ip_address_at default_value)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` unsigned_long_t

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format, unsigned_long_at default_value)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` unsigned_long_t

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format, num_at default_value)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` unsigned_long_t

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format, time_local_at default_value)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL

and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` unsigned_long_t

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format, time_at default_value)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` unsigned_long_t

`*TYPECAST_UNUM_TEXT_T`

Convert text_t to unum_text_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unum_text_t : Provides operations to treat the underlying OctectString as Binary String or unsigned long value .)

`Returns:` unum_text_t

`*TYPECAST_URL_CATEGORY_T`

Convert text_t to url_category_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (url_category_t : Retrieves URL category and attributes from an URL)

`Returns:` url_category_t

`*TYPECAST_VENDOR_SPEC_APPID_AVP_T`

Convert text_t to vendor_spec_appid_avp_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (vendor_spec_appid_avp_t : Retrieves AVPs that are nested in the grouped AVP Vendor-Specific-Application-Id (code 260). The nested AVPs are:

- Vendor-Id
- Auth-Application-Id
- Acct-Application-Id

For example, to retrieve the Auth-Application-Id AVP from the Vendor-Specific-Application-Id AVP:

- For requests: DIAMETER.REQ.VENDOR_SPECIFIC_APPLICATION_ID.AUTH_APPLICATION_ID
- For responses: DIAMETER.RES.VENDOR_SPECIFIC_APPLICATION_ID.AUTH_APPLICATION_ID

)

`Returns:` vendor_spec_appid_avp_t

`*TYPECAST_VENDOR_SPEC_RADIUS_AVP_T`

Convert text_t to vendor_spec_radius_avp_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (vendor_spec_radius_avp_t :

- Vendor-Id

To retrieve the Vendor-Id from the Vendor-Specific AVP:

- RADIUS.REQ.VENDOR_SPECIFIC.VENDORID

)

`Returns:` vendor_spec_radius_avp_t

`*UNQUOTE` (`char` c)

If selected text is quoted by character c, Remove character c from beginning and end.

For example: Say the selected text is / "foo xyz bar " /. Then on executing UNQUOTE("") the selected text will become /foo xyz bar / This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

c- Character

`Returns:` text_t

`*UNSIGNED16_STRING` (endian_e endianness)

Create an unsigned 16-bit binary string from the number.

`Parameters` (expressions not allowed) `:`

endianness- Select little or big endian

`Returns:` text_t

`*UNSIGNED32_STRING` (endian_e endianness)

Create an unsigned 32-bit binary string from the number.

`Parameters` (expressions not allowed) `:`

endianness- Select little or big endian

`Returns:` text_t

`*UNSIGNED64_STRING` (endian_e endianness)

Create an unsigned 64-bit binary string from the number.

`Parameters` (expressions not allowed) `:`

endianness- Select little or big endian

`Returns:` text_t

`*UNSIGNED8_STRING`

Create an unsigned 8-bit binary string from the number.

`Returns:` text_t

`*URLSET_MATCHES_ANY` (text_t urlset_name)

Results in Boolean TRUE value if and only if the Text matches any of the patterns that are specified in the urlset named by the string argument. The matching is case-insensitive for domains, but case-sensitive for paths. For example:

- HTTP.REQ.HOST.APPEND(HTTP.REQ.URL).URLSET_MATCHES_ANY("urlset_forbidden") returns true when the combined domain and URL matches any pattern in the urlset whose name is "urlset_forbidden".

`Parameters` (expressions not allowed) `:`

urlset_name- urlset name

`Returns:` bool_at

`*URL_CATEGORIZE` (`uint` min_reputation, `uint` max_reputation)

Returns the URL category for the supplied URL with the given minimum and maximum reputation score. Where a score of 5 is most risky and 1 is least risky. If either score is set to 0, that bound would be ignored. By specifying the reputation scores, the function will returned the category with the highest score (most risky) based on the bounds. If there was an error getting the category or if the URL is invalid then it will result in an Undef error. For example: HTTP.REQ.HOST.APPEND(HTTP.REQ.URL).URL_CATEGORIZE(0, 0) returns value when the combined domain and URL is looked up for the URL category with the highest reputation score (most risky).

`Parameters` (expressions not allowed) `:`

min_reputation- Minimum reputation score of URL category

max_reputation- Maximum reputation score of URL category

`Returns:` url_category_t

`*URL_RESERVED_CHARS_SAFE`

Converts URL reserved characters to corresponding '%XX' values and retains the rest. This is a read only operation.

```
Based on RFC3986, following are considered URL unreserved characters:

    Alpha-numeric characters: a-z, A-Z, 0-9

    Hyphen and underscore: "-", "_"

    Dot: "."

    Tilde: "~"
```

The rest are converted to %XX encoding, 'XX' is the hex-based representation of the input character. If the requirement is to encode all but URL safe characters, please consider using HTTP_URL_SAFE method.

`Returns:` text_t

`*VALUE` (`uint` lineno)

An HTTP header can have multiple occurrences. VALUE(0) will select the value in the last header line of the current type, VALUE(1) will select the value in the last but one header line and so on. The counting goes backward. Only the last 15 instances of a header are accessible. Therefore Instance Number cannot be greater than 14.

HTTP/1.1 200 OK\\r\\n MyHdr: abc\\r\\n Content-Length: 200\\r\\n MyHdr: def\\r\\n \\r\\n

For example: HTTP.RES.HEADER("MyHdr").VALUE(1) will return a Text object referring to "abc\\r\\n".

`Parameters` (expressions not allowed) `:`

lineno- Instance Number

`Returns:` text_t

`*WEEKDAY_STRING`

Given the numeric day of the week, e.g. SYS.TIME.WEEKDAY, return the long form of the string name for that day, e.g. 0 = "Sunday", 6 = "Saturday".

`Returns:` text_t

`*WEEKDAY_STRING_SHORT`

Given the numeric day of the week, e.g. SYS.TIME.WEEKDAY, return the short form of the string name for that day, e.g. 0 = "Sun", 6 = "Sat".

`Returns:` text_t

`*XML_DECRYPT` (text_t certKeyName)

Decrypt the selected content, which was encrypted using the W3C XML Encryption standard.

`Parameters` (expressions not allowed) `:`

certKeyName- identifies the certkey object containing the RSA private key to be used to decrypt the bulk encryption key in the selected EncryptedData element.

`Returns:` text_t

`*XML_ENCRYPT` (text_t certKeyName, encrypt_method_e method)

Encrypt the selected cleartext using the W3C XML Encryption standard.

`Parameters` (expressions not allowed) `:`

certKeyName- identifies the certkey object containing an X.509 certificate with the RSA public key to be used to encrypt the generated bulk encryption key. Note that the certKey object need not, and usually will not, include the associated RSA private key.

method- specifies the bulk encryption method (rc4, des3, aes128, aes192, or aes256) used to encrypt the content.

`Returns:` text_t

`*XML_ENCRYPT` (text_t certKeyName, encrypt_method_e method, `uint` flags)

Encrypt the selected cleartext using the W3C XML Encryption standard.

`Parameters` (expressions not allowed) `:`

certKeyName- identifies the certkey object containing an X.509 certificate with the RSA public key to be used to encrypt the generated bulk encryption key. Note that the certKey object need not, and usually will not, include the associated RSA private key.

method- specifies the bulk encryption method (rc4, des3, aes128, aes192, or aes256) used to encrypt the content.

flags- optional bit mask to specify optional elements in the EncryptedData element. These are hints to tell the receiver what private key to use to decrypt the bulk encryption key, providing information from the certKey's X.509 certificate.

- 1 - include a KeyName element with the certKeyName;
- 2 - include a KeyValue element with the RSA public key from the certificate;
- 4 - include an X509IssuerSerial element with the certificate serial number and issuer DN;
- 8 - include an X509SubjectName element with the certificate subject DN;
- 16 - include an X509Certificate element with the entire certificate;

`Returns:` text_t

`*XPATH_HTML_WITH_MARKUP` (`xpath_str` xpathex)

Applies an XPath expression to the DOM for an HTML document and returns the selected node-set or string, including markup like element tags. node-sets are converted to strings using the standard XPath string conversion routine. The selected portion of the document can be used as the target for rewrite actions.

Examples: HTTP.REQ.BODY(1000).XPATH_HTML_WITH_MARKUP(xp%//md/head/title%) returns the <title> element in the document's <head> This can be used in a rewrite action to replace or delete the <title> element.

`Parameters` (expressions not allowed) `:`

xpathex- XPath Expression

`Returns:` text_t

`*XPATH_HTML` (`xpath_bool` xpathex)

Applies an XPath expression to the DOM for an HTML document and a boolean value.

Examples: HTTP.RES.BODY(1000).XPATH_HTML(xp%boolean(/md/head/meta)%) returns true if the <meta> element exists as a child of <head> element.

`Parameters` (expressions not allowed) `:`

xpathex- XPath Expression

`Returns:` bool_at

`*XPATH_HTML` (`xpath_double` xpathex)

Applies an XPath expression to the DOM for an HTML document and a double value.

Examples: HTTP.RES.BODY(1000).XPATH_HTML(xp%number(//video/@height)%) returns the numeric value of the height attribute of the first <video> element.

`Parameters` (expressions not allowed) `:`

xpathex- XPath Expression

`Returns:` double_at

`*XPATH_HTML` (`xpath_str` xpathex)

Applies an XPath expression to the DOM for an HTML document and returns the selected node-set or string. node-sets are converted to strings using the standard XPath string conversion routine.

Examples: HTTP.REQ.BODY(1000).XPATH_HTML(xp%//img/@src%) returns the string value of the src attribute of the first

HTTP_COOKIE_T

This object provides operations for parsing the HTTP cookie header. The name-value pair is derived from the value in the last instance of Cookie header. The format is Cookie : name0=value0; name1=value1; An HTTP Cookie header can have multiple occurrences. COUNT will return a Number containing how many headers of the current type exist. The name comparison for all list operations is case insensitive. The system does not keep track of more than 15 HTTP headers. The result will be undefined if there are more than 15 instances of the header.

This topic lists the expressions that are provided by this class.

`*Note` *: Expressions with the * symbol are inherited / promoted from http_header_t nvlist_at

- `TYPECAST_HTTP_HEADER_T`

  Convert http_cookie_t to http_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_header_t : Typecast an HTTP Header object of a specific type to HTTP Header.For example: HTTP.REQ.CONTENT_LENGTH.TYPECAST_HTTP_HEADER_T)

`Returns:` http_header_t

`*AFTER_REGEX` (`re` regex)

The AFTER_REGEX operator in this object overrides the Text AFTER_REGEX operator to operate on all the instances of the current header type. Selects the Text after the text that matches the input regular expression in any instance of the header value. The order in which the header instances will be matched is from the last to the first.

For example: HTTP.REQ.HEADER("etag").AFTER_REGEX(re/KX/) will select "DAPPER" from "KXDAPPER". This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

regex- Regular Expression

`Returns:` text_t

`*AFTER_STR_ANY` (text_t patset_name)

Selects the Text that is present after the first occurrence of any of the strings that are bound to the patset named by the string argument. If there is no match to any of the strings bound to the patset in the current Text object then the result Text object has 0 length. The patset cannot have strings longer than 255 characters. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` text_t

`*AFTER_STR` (text_t s)

The AFTER_STR operator in this object overrides the Text AFTER_STR operator to operate on all the instances of the current header type. Selects Text after the first occurrence of the input string argument. The order in which the instances of the header are matched is from the last instance to the first.

HTTP/1.1 200 OK\\r\\n MyHdr: 111abc\\r\\n Content-Length: 200\\r\\n MyHdr: 111def\\r\\n \\r\\n

Examples: HTTP.RES.HEADER("MyHdr").AFTER_STR("111") selects "def" in the last instance of MyHdr, the one with value "111def". HTTP.RES.HEADER("MyHdr").AFTER_STR("1ab") selects "c" in the first instance of MyHdr, the one with value "abc111". This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*APPEND` (bool_at b)

Appends the given boolean's string representation to the current string.

`Parameters``:`

b- the boolean value to append.

`Returns:` text_t

`*APPEND` (double_at i)

Appends the given double's string representation to the current string.

`Parameters``:`

i- the double value to append.

`Returns:` text_t

`*APPEND` (ip_address_at addr)

Appends the given IPv4's string representation to the current string.

`Parameters``:`

addr- the IPv4 address to append.

`Returns:` text_t

`*APPEND` (num_at i)

Appends the given number's string representation to the current string.

`Parameters``:`

i- the number value to append.

`Returns:` text_t

`*APPEND` (time_local_at t)

Appends the given time's string representation to the current string.

`Parameters``:`

t- the time value to append.

`Returns:` text_t

`*APPEND` (time_at t)

Appends the given time's string representation to the current string.

`Parameters``:`

t- the time value to append.

`Returns:` text_t

`*APPEND` (unsigned_long_at i)

Appends the given unsigned long's string representation to the current string.

`Parameters``:`

i- the unsigned long value to append.

`Returns:` text_t

`*APPEND` (ipv6_address_at addr)

Appends the given IPv6's string representation to the current string.

`Parameters``:`

addr- the IPv6 address to append.

`Returns:` text_t

`*APPEND` (ipv6_subnet_at addr)

Appends the given IPv6 subnet's string representation to the current string.

`Parameters``:`

addr- the IPv6 subnet to append.

`Returns:` text_t

`*APPEND` (mac_address_at addr)

Appends the given MAC's string representation to the current string.

`Parameters``:`

addr- the MAC address to append.

`Returns:` text_t

`*APPEND` (text_t str)

Appends the given string to the current string.

`Parameters``:`

str- the string to append.

`Returns:` text_t

`*APPEND` (time_at t)

Appends the given time's string representation to the current string.

`Parameters``:`

t- the time value to append.

`Returns:` text_t

`*B64DECODE`

Decodes the selected text using base64 decoding.

For example, the string "TWFu" is converted to "Man"

`Returns:` text_t

`*B64ENCODE`

Encodes the selected text using base64 encoding.

For example, the string "Man" is converted to "TWFu"

`Returns:` text_t

`*BEFORE_REGEX` (`re` regex)

The BEFORE_REGEX operator in this object overrides the Text BEFORE_REGEX operator to operate on all the instances of the current header type. Selects the Text before the text that matches the input regular expression in any instance of the header value. The order in which the header instances will be matched is from the last to the first.

For example: HTTP.RES.HEADER("content-type").BEFORE_REGEX(re#/#) will select "text" from "text/plain". This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

regex- Regular Expression

`Returns:` text_t

`*BEFORE_STR_ANY` (text_t patset_name)

Selects the Text that is present before the first occurrence of any of the strings that are bound to the patset or datasetnamed by the string argument. If there is no match to any of the strings bound to the patset in the current Text object then the result Text object has 0 length. The patset cannot have strings longer than 255 characters. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` text_t

`*BEFORE_STR` (text_t s)

The BEFORE_STR operator in this object overrides the Text BEFORE_STR operator to operate on all the instances of the current header type. Selects Text before the first occurrence of the input string argument. The order in which the instances of the header are matched is from the last instance to the first.

HTTP/1.1 200 OK\\r\\n MyHdr: abc111\\r\\n Content-Length: 200\\r\\n MyHdr: def111\\r\\n \\r\\n

Examples: HTTP.RES.HEADER("MyHdr").BEFORE_STR("111") selects "def" in the last instance of MyHdr, the one with value "def111". HTTP.RES.HEADER("MyHdr").BEFORE_STR("bc1") selects "a" in the first instance of MyHdr, the one with value "abc111". This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*BETWEEN` (text_t start, text_t end)

Results in Boolean TRUE value if length of the Text object is greater than or equal to the sum of the Start and End argument lengths and if the prefix of the Text object matches the Start string argument and if the Suffix of the Text object matches the End string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

start- Start

end- End

`Returns:` bool_at

`*BIN_DECODE` (binary_encoding_e encoding)

Decode the encoded input into its original byte sequence. An incorrectly enooded input will result in an Undef error.

`Parameters` (expressions not allowed) `:`

encoding- specifies how the bytes are encoded.

`Returns:` text_t

`*BIN_ENCODE` (binary_encoding_e encoding)

Encode the input byte sequence. Note that BIN_ENCODE(hex_colons) is equivalent to BLOB_TO_HEX().

`Parameters` (expressions not allowed) `:`

encoding- specifies how the bytes are to be encoded.

`Returns:` text_t

`*BLOB_TO_HEX`

Convert to hexadecimal representation and select text.

For example, the byte string abc is converted to 61:62:63.

`Returns:` text_t

`*COMPARE` (text_t s)

Results in a Number Value which is the result of comparison of the input argument with the Text object. The result is greater than 0 if the Text object is lexicographically greater than the argument. The result is 0 if the Text object and the argument match. The result is less than 0 if the Text object is lexicographically lesser than the argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` num_at

`*CONTAINS_ANY` (text_t patclass_name)

The CONTAINS_ANY in this object overrides the Text CONTAINS_ANY operator to operate on all the instances of the current header type. Returns Boolean TRUE if any of the patterns associated with input patclass is present in any instance of the header value. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patclass_name- Patclass Name

`Returns:` bool_at

`*CONTAINS_INDEX` (text_t patclass_name)

The CONTAINS_INDEX in this object overrides the Text CONTAINS_INDEX operator to operate on all the instances of the current header type. Returns the index of the matching pattern associated with input patclass that is present in any instance of the header value. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patclass_name- Patclass Name

`Returns:` num_at

`*CONTAINS` (text_t s)

The CONTAINS in this object overrides the Text CONTAINS operator to operate on all the instances of the current header type. Returns Boolean TRUE if the input Pattern String is present in any instance of the header value.

GET / HTTP/1.1\\r\\n Host: abc.com\\r\\n MyHdr: abc\\r\\n Content-Length: 200\\r\\n MyHdr: def\\r\\n

HTTP/1.1 200 OK\\r\\n MyHdr: abc\\r\\n Content-Length: 200\\r\\n MyHdr: def\\r\\n \\r\\n

Examples: HTTP.RES.HEADER("MyHdr").CONTAINS("de") is TRUE.
HTTP.RES.HEADER("MyHdr").CONTAINS("bcd") is FALSE.
HTTP.REQ.HEADER("MyHdr").CONTAINS("de") is TRUE.
HTTP.REQ.HEADER("MyHdr").CONTAINS("bcd") is FALSE. The system does not concatenate the different values. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- Pattern String

`Returns:` bool_at

`*COUNT`

Return a Number Value giving the number of name-value components in the list. If the last Name-Value List component is of zero length or is all spaces then it is ignored.

`Returns:` num_at

`*CRC32`

Returns a 32-bit integer computed by applying a CRC (cyclic redundancy check) function to the selected text. This is the CRC function used by Ethernet, MPEG-2, PKZIP, GZIP, PNG, and many other applications. For example, the expression to compute the CRC value of the (first 1000 bytes of the) body of an HTTP request is: HTTP.REQ.BODY(1000).CRC32

`Returns:` num_at

`*DECODE_USING_TEXT_MODE`

Decodes the selected text using the currently configured text encoding methods like URLENCODED, BACKSLASH_ENCODED, PLUS_AS_SPACE, NOURLENCODED, NO_BACKSLASH_ENCODED and NO_PLUS_AS_SPACE. Text encoding methods are set using SET_TEXT_MODE method.

`Returns:` text_t

`*DECRYPT`

Decrypt the selected base64-encoded ciphertext using the configured encryptionParams.

`Returns:` text_t

`*DECRYPT` (binary_encoding_e in_encoding)

Decrypt the selected ciphertext using the configured encryptionParams.

`Parameters` (expressions not allowed) `:`

in_encoding- specifies how the input ciphertext is encoded. If the ciphertext is not encoded as specified, causes an Undef error.

`Returns:` text_t

`*DECRYPT` (text_t encryptionKey)

Decrypt the selected base64-encoded encrypted bytes using the configured encryption key.

`Parameters` (expressions not allowed) `:`

encryptionKey- identifies the encryptionKey object to provide the cipher method, mode, padding, key, encrypted format and optional initialization vector (IV).

`Returns:` text_t

`*DECRYPT` (text_t encryptionKey, binary_encoding_e in_encoding)

Decrypt the selected base64-encoded encrypted bytes using the configured encryption key.

`Parameters` (expressions not allowed) `:`

encryptionKey- identifies the encryptionKey object to provide the cipher method, mode, padding, key, encrypted format, and optional initialization vector (IV).

in_encoding- specifies how the input ciphertext is encoded. If the ciphertext is not encoded as specified, causes an Undef error.

`Returns:` text_t

`*DIGEST` (digest_method_e method)

Returns a byte sequence computed by applying the the specified message digest method to the selected text.

`Parameters` (expressions not allowed) `:`

method- digest method to apply to the input text

`Returns:` text_t

`*ENCRYPT`

Encrypt the selected plaintext bytes using the configured encryptionParams. The resulting ciphertext is base64-encoded.

`Returns:` text_t

`*ENCRYPT` (binary_encoding_e out_encoding)

Encrypt the selected plaintext bytes using the configured encryptionParams.

`Parameters` (expressions not allowed) `:`

out_encoding- specifies how the resulting ciphertext is encoded.

`Returns:` text_t

`*ENCRYPT` (text_t encryptionKey)

Encrypt the selected cleartext bytes using the configured encryption key.

`Parameters` (expressions not allowed) `:`

encryptionKey- identifies the encryptionKey object to provide the cipher method, mode, padding, key, encrypted format and optional initialization vector (IV).

`Returns:` text_t

`*ENCRYPT` (text_t encryptionKey, binary_encoding_e out_encoding)

Encrypt the selected cleartext bytes using the configured encryption key.

`Parameters` (expressions not allowed) `:`

encryptionKey- identifies the encryptionKey object to provide the cipher method, mode, padding, key, encrypted format and optional initialization vector (IV).

out_encoding- specifies how the resulting ciphertext is encoded.

`Returns:` text_t

`*ENDSWITH_ANY` (text_t patset_name)

Results in Boolean TRUE value if the Text ends with any of the strings that are bound to the patset or dataset named by the string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` bool_at

`*ENDSWITH_INDEX` (text_t patset_name)

Returns the numerical index of the matching string, if the Text ends with any of the strings that are bound to the patset or dataset named by the string argument. Returns 0 if there is no match. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` num_at

`*ENDSWITH` (text_t end)

Results in Boolean TRUE value if a suffix of the Text object matches the string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

end- String

`Returns:` bool_at

`*EQUALS_ANY` (text_t patset_name)

The EQUALS_ANY in this object overrides the Text EQUALS_ANY operator to operate on all the instances of the current header type. Returns Boolean TRUE if any of the patterns associated with input patset is equal to any instance of the header value. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Patset Name

`Returns:` bool_at

`*EQUALS_INDEX` (text_t patset_name)

The EQUALS_INDEX in this object overrides the Text EQUALS_INDEX operator to operate on all the instances of the current header type. Returns the index of the matching pattern associated with input patset is equal to any instance of the header value. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Patset Name

`Returns:` num_at

`*EQ` (text_t s)

Results in Boolean TRUE value if the Text object matches the input argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*EXISTS`

Returns TRUE if an instance of the current header type exists.

`Returns:` bool_at

`*GET_SIGNED16` (`uint` n, endian_e endianness)

Get the 16-bit signed binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

endianness- Select little or big endian

`Returns:` num_at

`*GET_SIGNED32` (`uint` n, endian_e endianness)

Get the 32-bit signed binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

endianness- Select little or big endian

`Returns:` num_at

`*GET_SIGNED8` (`uint` n)

Get the 8-bit signed binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

`Returns:` num_at

`*GET_UNSIGNED16` (`uint` n, endian_e endianness)

Get the 16-bit unsigned binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

endianness- Select little or big endian

`Returns:` num_at

`*GET_UNSIGNED32` (`uint` n, endian_e endianness)

Get the 32-bit unsigned binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

endianness- Select little or big endian

`Returns:` unsigned_long_at

`*GET_UNSIGNED64` (`uint` n, endian_e endianness)

Get the 64-bit unsigned binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

endianness- Select little or big endian

`Returns:` unsigned_long_at

`*GET_UNSIGNED8` (`uint` n)

Get the 8-bit unsigned binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

`Returns:` num_at

`*GET_URLSET_METADATA` (text_t urlset_name)

Returns metadata value corresponding to pattern in the urlset. The matching is case-insensitive for domains, but case-sensitive for paths. If no pattern is matched within the urlset, the return value is a NULL string. For example:

- HTTP.REQ.HOST.APPEND(HTTP.REQ.URL).GET_URLSET_METADATA("urlset_forbidden") returns value when the combined domain and URL is looked up in the urlset whose name is "urlset_forbidden".

`Parameters` (expressions not allowed) `:`

urlset_name- urlset name

`Returns:` text_t

`*GE` (text_t s)

Results in Boolean TRUE value if the Text object is greater than or equal to the input argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*GRPC`

Interprets a text_t string as a Protocol Buffer (protocol_buffer_t type). Example: HTTP.REQ.BODY(1000).GRPC.STRING(1).EQ("bookname")

`Returns:` protocol_buffer_t

`*GT` (text_t s)

Results in Boolean TRUE value if the Text object is greater than the input argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*HASH`

Returns a positive 31 bit integer value computed by applying a proprietary NetScaler hash function to the selected text. This function is not case- sensitive and ignores whitespaces. For example, applying the HASH function to two strings "Ab c" and "abc" would produce the same value. This function should not be used for security purposes; use instead the DIGEST function with one of the standard digest methods.

`Returns:` num_at

`*HMAC` (text_t hmacKey)

Returns a byte sequence computed by applying the HMAC (Hash Message Authenticastion Code) function to the selected text using the configured HMAC key.

`Parameters` (expressions not allowed) `:`

hmacKey- indentifies the hmacKey object to provide the digest (hash) method and the key.

`Returns:` text_t

`*HMAC` (text_t hmacKey, binary_encoding_e out_encoding)

Returns a byte sequence computed by applying the HMAC (Hash Message Authenticastion Code) function to the selected text using the configured HMAC key .

`Parameters` (expressions not allowed) `:`

hmacKey- indentifies the hmacKey object to provide the digest (hash) method and the key.

out_encoding- specifies how the resulting HMAC is encoded.

`Returns:` text_t

`*HTML_XML_SAFE`

Apply XML safe transform and select text.

Converts '<', '>' and '&' in the input text to '<', '>' and '&' respectively; other characters in the input are not modified. This transform safeguards against XSS based attacks. This is a read only operation.

`Returns:` text_t

`*HTTP_HEADER_SAFE`

Apply Header safe transform and select text. Converts all new line ('\\n') characters present in the input text to '%0A' so that they can safely be used in HTTP headers. This transform safeguards against response-splitting attacks. This is a read only operation.

`Returns:` text_t

`*HTTP_URL_SAFE`

Apply URL safe transform and select text. Converts URL unsafe characters to corresponding '%xx' values and retains the rest. This is a read only operation.

```
Based on RFC2396, following are considered URL safe characters:

    Alpha-numeric characters: a-z, A-Z, 0-9

    Hyphen and underscore: "-", "_"

    Dot: "."

    Exclamation mark: "!"

    Tilde: "~"

    Asterix: "&ast;"

    Single quote: "'"

    Open and close parentheses: "(", ")"

    Semi-colon: ";"

    Colon: ":"

    At symbol: "@"

    Question mark: "?"

    Equals: "="
```

```
    Dollar: "$"

    Percent: "%"

    Ampersand: "&"

    Plus: "+"

    Comma: ","

    Forward slash: ".html"
```

The rest are converted to %XX encoding, 'XX' is the hex-based representation of the input character. If the requirement is to encode all but URL unreserved characters, please consider using URL_RESERVED_CHARS_SAFE method.

`Returns:` text_t

`*INSTANCE` (`uint` lineno)

An HTTP header can have multiple occurrences. INSTANCE(0) will select the last header line of the current type, INSTANCE(1) will select the last but one header line and so on. The counting goes backward. Only the last 15 instances of a header are accessible. Therefore Instance Number cannot be greater than 14.

HTTP/1.1 200 OK\\r\\n MyHdr: abc\\r\\n Content-Length: 200\\r\\n MyHdr: def\\r\\n \\r\\n

For example: HTTP.RES.HEADER("MyHdr").INSTANCE(1) will return a Text object referring to "MyHdr: abc\\r\\n". It can not be used in HTTP response processing contexts.

`Parameters` (expressions not allowed) `:`

lineno- Instance Number

`Returns:` text_t

`*IS_BOOL_AT`

Results in Boolean TRUE value if the Text is of boolean type.

`Returns:` bool_at

`*IS_DOUBLE_AT`

Results in Boolean TRUE value if the Text is of double data type.

`Returns:` bool_at

`*IS_IPV6_AT`

Results in Boolean TRUE value if the Text is of IPv6 data type.

`Returns:` bool_at

`*IS_IPV6_SUBNET_AT`

Results in Boolean TRUE value if the Text is of IPv6 subnet data type.

`Returns:` bool_at

`*IS_IP_AT`

Results in Boolean TRUE value if the Text is of IPv4 data type.

`Returns:` bool_at

`*IS_MAC_ADDRESS_AT`

Results in Boolean TRUE value if the Text is of mac address data type.

`Returns:` bool_at

`*IS_NUM_AT`

Results in Boolean TRUE value if the Text is of number type.

`Returns:` bool_at

`*IS_NUM_AT` (num_format_e format)

Results in Boolean TRUE value if the Text is of number type with given input base.

`Parameters` (expressions not allowed) `:`

format- number format

`Returns:` bool_at

`*IS_STRINGMAP_KEY` (text_t string_map_name)

Returns true if the string that it operates on is present in the string map. Text mode IGNORECASE, NOIGNORECASE - controls whether key lookup in string map is case sensitive or not. For example:

- HTTP.REQ.URL.IS_STRINGMAP_KEY("url_stringmap") returns true if value of HTTP.REQ.URL is present as key in the string map whose name is "url_stringmap".
- HTTP.REQ.URL.SET_TEXT_MODE(IGNORECASE). IS_STRINGMAP_KEY("url_stringmap") returns true if value of HTTP.REQ.URL is present as key in the string map whose name is "url_stringmap". Key lookup in this case is done case-insensitively.

`Parameters` (expressions not allowed) `:`

string_map_name- identifies the string map.

`Returns:` bool_at

`*IS_TIME_AT`

Results in Boolean TRUE if the Text follows any of the standard time formats given below, otherwise false. Tue, 05 Nov 1994 08:12:31 GMT RFC822 Tuesday, 05-Nov-94 08:12:31 GMT RFC850 Tue Nov 4 08:12:31 1994 asctime

`Returns:` bool_at

`*IS_UNSIGNED_LONG_AT`

Results in Boolean TRUE value if the Text is of unsigned long data type.

`Returns:` bool_at

`*IS_UNSIGNED_LONG_AT` (num_format_e format)

Results in Boolean TRUE value if the Text is of unsigned long data type with given input base.

`Parameters` (expressions not allowed) `:`

format- number format

`Returns:` bool_at

`*JWT_VERIFY_CERTKEY` (text_t certkey_name)

Verifies the signature on the input JSON Web Token (JWT), using the RSA public key in the X.509 certificate in the specified certkey object. The token has the format HEADER.PAYLOAD.SIGNATURE where

- HEADER is a base64-encoded JSON structure indicating a signature algorithm and token type, e.g.'{"alg":"RS256","typ":"JWT"}'
- PAYLOAD is a base64-encoded JSON structure with asserted claims, e.g. '{"loggedInAs":"admin","iat":1422779638}'
- SIGNATURE is the base64-encoded bytes for the signature on HEADER.PAYLOAD.

Returns true if the signature is verified for the header and payload using the specified public key; false if the signature is not verified

`Parameters``:`

certkey_name- identifies the certkey object containing an X.509 certificate holding the RSA public key. Results in an Undef error if the certkey object does not exist or does not contain an X.509 certificate with an RSA public key, if the token is not correctly formatted, or if the verification operation cannot complete.

`Returns:` bool_at

`*JWT_VERIFY_XML` (text_t xml_pkey)

Verifies the signature on the input JSON Web Token (JWT), using the RSA public key supplied by the specified XML element. The token has the format HEADER.PAYLOAD.SIGNATURE where

- HEADER is a base64-encoded JSON structure indicating a signature algorithm and token type, e.g.'{"alg":"RS256","typ":"JWT"}'
- PAYLOAD is a base64-encoded JSON structure with asserted claims, e.g. '{"loggedInAs":"admin","iat":1422779638}'
- SIGNATURE is the base64-encoded bytes for the signature on HEADER.PAYLOAD.

Returns true if the signature is verified for the header and payload using the specified public key; false if the signature is not verified

`Parameters``:`

xml_pkey- an expression that supplies an <RSAKeyValue> element with the public key. Results in an Undef error if the XML element is invalid or does not correctly specify an RSA public key, if the token is not correctly formatted, or if the verification operation cannot complete.

`Returns:` bool_at

`*LENGTH`

Results in a Number Value that is the number of characters (not bytes) in the Text object.

`Returns:` num_at

`*LE` (text_t s)

Results in Boolean TRUE value if the Text object is less than or equal to the input argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*LOCATION_LONG`

Get the location qualifier from CLIENT.IP.SRC.LOCATION.GET(n) (ISO short name) and then convert it to human readable long name. This conversion is valid only for country names. Correct Country qualifier value (number) in GET(n) is left up to the user as qualifiers are user configurable. Expression example: CLIENT.IP.SRC.LOCATION.GET(1).LOCATION_LONG For example: Data from each expression CLIENT.IP.SRC.LOCATION: NA.US.California.SantaClara.*.* CLIENT.IP.SRC.LOCATION.GET(1): US CLIENT.IP.SRC.LOCATION.GET(1).LOCATION_LONG: United States

`Returns:` text_t

`*LT` (text_t s)

Results in Boolean TRUE value if the Text object is less than the input argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*MAP_STRING_DEFAULT_TO_KEY` (text_t string_map_name)

Returns the value corresponding to the key in the string map. This is similar to the MAP_STRING method, but if the key is not present then instead of returning a null string, it returns the key itself. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

string_map_name- identifies the string map.

`Returns:` text_t

`*MAP_STRING` (text_t string_map_name)

Returns value corresponding to key in the string map. Key is the string that it is given as input. Text mode IGNORECASE, NOIGNORECASE - controls whether key lookup in string map is case sensitive or not. For example:

- HTTP.REQ.URL.MAP_STRING("url_stringmap") returns value when the value of HTTP.REQ.URL is used as key in the string map whose name is "url_stringmap".
- HTTP.REQ.URL.SET_TEXT_MODE(IGNORECASE). MAP_STRING("url_stringmap") returns value when the value of HTTP.REQ.URL is used as key in the string map whose name is "url_stringmap". Key lookup in this case is done case-insensitively.

`Parameters` (expressions not allowed) `:`

string_map_name- identifies the string map.

`Returns:` text_t

`*MARK_SAFE`

Mark the PIXL expression safe without applying any safe transform.

`Returns:` text_t

`*MAX` (text_t s)

Compares the string argument with the current string and returns the max string. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*MIN` (text_t s)

Compares the string argument with the current string and returns the min string. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*NAMES`

Extracts a list of only the names from the name-value pair list. For example the list 'a=b,c="d=e,f",g=h' will result in the list 'a,c,g'. Empty elements will be ignored.

`Returns:` list_t

`*NAME` (`uint` i)

Operate as Text on the name component of the specified name-value component in the list. The index of the name-value component given by the argument is 0-based. If the specified index is greater than the number of components then a zero length Text object is produced.

`Parameters` (expressions not allowed) `:`

i- Index

`Returns:` text_t

`*NAME_VALUE` (`uint` i)

Returns the element in the list identified by the parameter. The parameter is a 0-based index in to the list. The result is a string. If the specified index is greater than the number of components then a zero length string is produced.

`Parameters` (expressions not allowed) `:`

i- Index

`Returns:` text_t

`*NAME_VALUE` (text_t name)

Operate as Text on the name-value component in the list. The name-value component is specified by the argument by providing the name whose name-value is needed. The first component that matches the name is selected. The matching process honors the IGNORECASE and the NOIGNORECASE text modes. The URLENCODED and the NOURLENCODED text modes are ignored.

`Parameters` (expressions not allowed) `:`

name- Name

`Returns:` text_t

`*NAME_VALUE` (text_t name, `uint` i)

Operate as Text on the name-value component in the list. The name-value component is specified by the argument by providing the name whose name-value is needed. In a name-value list the same name can be repeated multiple times. The Index argument controls which occurence of the matching name-value component should be selected. The Index is 0-based. If the Index is too big then the Text object that is produced will have zero length. The matching process honors the IGNORECASE and the NOIGNORECASE text modes. The URLENCODED and the NOURLENCODED text modes are ignored.

`Parameters` (expressions not allowed) `:`

name- Name

i- Index

`Returns:` text_t

`*NE` (text_t s)

Results in Boolean TRUE value if the Text object is not equal to the input argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*NORMALIZE_URL`

Normalize URL. Normalizes a URL by doing "percent" decoding. See the description for URLENCODED in the SET_TEXT_MODE function. This performs the equivalent of SET_TEXT_MODE(URLENCODED).DECODE_USING_TEXT_MODE, except that it does not change the value of the current text mode.

`Returns:` text_t

`*PKEY_ENCRYPT_PEM_NO_PADDING` (text_t pem_pkey)

Encrypts the input text using the RSA public key provided by the PEM string and RSA_NO_PADDING padding method. The input text to be encrypted cannot be longer than the public key length minus 11 bytes for padding. For example, for a 1024-bit (128 byte) key, the input text cannot be longer than 128 - 11 = 117 bytes. An Undef error will occur if the input text is too long. A null input will also cause an Undef error. Returns the (unencoded binary) encrypted text, which is typically base-64 encoded for use in a message.

`Parameters``:`

pem_pkey- a text expression that supplies a RSA public key in the PEM format. If the text value is not a valid PEM RSA PUBLIC KEY encoding, an Undef error will occur. Example (a 1024-bit public key):

```
"-----BEGIN RSA PUBLIC KEY-----" +

"MIGJAoGBAKl5vgQEj73Kxp+9yn1v5gPR1pnc4oLM2a0kaWwBOsB6rzCIy6znwnvw" +

"CY1xRvQhRlJSAyJbloL7wZFIJ2FOR8Cz+8ZQWXU2syG+udi4EnWqLgFYowF9zK+o" +

"79az597eNPAjsHZ/C2oL/+6qY5a/f1z8bQPrHC4GpFfAEJhh/+NnAgMBAAE=" +

"-----END RSA PUBLIC KEY-----"
```

`Returns:` text_t

`*PKEY_ENCRYPT_PEM` (text_t pem_pkey)

Encrypts the input text using the RSA public key provided by the PEM string and the RSA_PKCS1_PADDING padding method. The input text to be encrypted cannot be longer than the public key length minus 11 bytes for padding. For example, for a 1024-bit (128 byte) key, the input text cannot be longer than 128 - 11 = 117 bytes. An Undef error will occur if the input text is too

long. A null input will also cause an Undef error. Returns the (unencoded binary) encrypted text, which is typically base-64 encoded for use in a message.

`Parameters``:`

pem_pkey- a text expression that supplies a RSA public key in the PEM format. If the text value is not a valid PEM RSA PUBLIC KEY encoding, an Undef error will occur. Example (a 1024-bit public key):

```
"-----BEGIN RSA PUBLIC KEY-----" +

"MIGJAoGBAKl5vgQEj73Kxp+9yn1v5gPR1pnc4oLM2a0kaWwBOsB6rzCIy6znwnvw" +

"CY1xRvQhRlJSAyJbloL7wZFIJ2FOR8Cz+8ZQWXU2syG+udi4EnWqLgFYowF9zK+o" +

"79az597eNPAjsHZ/C2oL/+6qY5a/f1z8bQPrHC4GpFfAEJhh/+NnAgMBAAE=" +

"-----END RSA PUBLIC KEY-----"
```

`Returns:` text_t

`*PKEY_SIGN_CERTKEY` (text_t certkey_name)

Generates a binary digital signature using the SHA-256 message digest function and an RSA private key from the specified SSL certKey object.

`Parameters``:`

certkey_name- identifies the configured certKey object. Results in an Undef error if the certkey object does not exist or does not contain an RSA private key, or if the signing operation cannot complete.

`Returns:` text_t

`*PKEY_SIGN_XML` (text_t xml_pkey)

Generates a binary digital signature using the SHA-256 message digest function and an RSA private key from the specified XML element.

`Parameters``:`

xml_pkey- an expression that supplies an <RSAKeyValue> element with the private key. Example: <RSAKeyValue> <Modulus>qXm+BASPvcrGn73KfW/
mA9HWmdzigszZrSRpbAE6wHqvMIjLrOfCe/
AJjXFG9CFGUlIDIluWgvvBkUgnYU5HwLP7xlBZdTazIb652LgSdaouAVijAX3Mr6jv1rPn3t408COwdn8Lagv/
7qpjlr9/XPxtA+scLgakV8AQmGH/42c=</Modulus> <Exponent>AQAB</Exponent>"zNjysxcIJV/

5JJpPGZ69ovDFEVOUHyiCfKE/g97T4WX3us0nFe1272zwGlHarM1YYwvfeE08UdE=</D> </
RSAKeyValue> Results in an Undef error if the XML element is invalid or does not correctly specify an RSA private key, or if the signing operation cannot complete.

`Returns:` text_t

`*PKEY_VERIFY_CERTKEY` (text_t certkey_name, text_t signature)

Verifies if the input text matches the specified signature generated using the SHA-256 messge digest function and the RSA private key associated with the specified RSA public key in the X.509 certificate in the specified certKey object. Returns true if the signature is verified, false otherwise.

`Parameters``:`

certkey_name- identifies the certkey object containing an X.509 certificate holding the RSA public key.

signature- the binary signature. Results in an Undef error if the certkey object does not exist or does not contain an X.509 certificate with an RSA public key, or if the verification operation cannot complete.

`Returns:` bool_at

`*PKEY_VERIFY_XML` (text_t xml_pkey, text_t signature)

Verifies if the input text matches the specified signature generated using the SHA-256 messge digest function and the RSA private key associated with the RSA public key supplied by the specified XML element. Returns true if the signature is verified, false otherwise.

`Parameters``:`

xml_pkey- an expression that supplies an <RSAKeyVAlue> element with the public key. Example: <RSAKeyValue> <Modulus>qXm+BASPvcrGn73KfW/mA9HWmdzigszZrSRpbAE6wHqvMIjLrOfCe/AJjXFG9CFGUlIDIluWgvvBkUgnYU5HwLP7xlBZdTazIb652LgSdaouAVijAX3Mr6jv1rPn3t408COwdn8Lagv/7qpjlr9/XPxtA+scLgakV8AQmGH/42c=</Modulus> <Exponent>AQAB</Exponent> </RSAKeyValue>

signature- the binary signature. Results in an Undef error if the XML element is invalid or does not correctly specify an RSA public key, or if the verification operation cannot complete.

`Returns:` bool_at

`*PREFIX` (`char` c, `uint` i)

Select a prefix of the Text. The selected prefix is the longest prefix that has at most Count (2nd argument) occurrences of character in the 1st argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

c- Character

i- Count

`Returns:` text_t

`*PREFIX` (`uint` i)

Select a prefix of the Text. The length of the prefix is equal to the number in the argument. If there aren't enough characters in the Text object then the entire Text is selected.

`Parameters``:`

i- Prefix Length

`Returns:` text_t

`*REGEX_MATCH` (`re` regex)

The REGEX_MATCH operator in this object overrides the Text REGEX_MATCH operator to operate on all the instances of the current header type. Returns Boolean TRUE if the input regular

expression matches any instance of the header value. The order in which the header instances will be matched is from the last to the first.

The regular expression has to be of the format: `re<delimiter>regular expression<same delimiter>`

The regular expression cannot be bigger than 1499 characters.

The regular expression should be acceptable by the PCRE regular expression library. Look at http://www.pcre.org/pcre.txt for documentation on the regular expression syntax. In particular, look at the pcrepattern man page.

There are some differences in the allowed syntax w.r.t PCRE syntax. Backreferences are not allowed. It is recommended to not use recursive regular expressions. The dot metacharacter matches newlines also. Unicode is not supported. SET_TEXT_MODE(IGNORECASE) overrides the (?i) internal option specified in the regular expression.

The PCRE library configuration can be seen in the system log, after executing 'nsapimgr -B" call ns_pixl_regex_show_config()"' at the shell prompt.

Some examples:

- HTTP.REQ.HOSTNAME.REGEX_MATCH(re/\[\[:alpha:\]\]+(abc){2,3}/)
- HTTP.REQ.URL.SET_TEXT_MODE(URLENCODED).REGEX_MATCH(re#(a*b+c*)#)
- HTTP.REQ.URL.REGEX_MATCH(re/a(?i)b/) matches ab and aB
- HTTP.REQ.URL.SET_TEXT_MODE(IGNORECASE).REGEX_MATCH(re/ab/) matches ab, aB, Ab and AB
- HTTP.REQ.BODY.REGEX_MATCH(re/(?ixm) (\^ab (.*) cd$) /) does a case-insensitive, multiline match where the dot metacharacter matches newline also. The regex itself can contain whitespace which will be ignored during the matching (x - extended regex).

This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

regex- Regular Expression

`Returns:` bool_at

`*REGEX_REPLACE` (`re` regex, text_t replacement, replacemode_e mode)

Selects the text that matches the given regular expression argument and replaces it with the the text given in the second argument. The third argument specifies whether the first match is only replaced when multiple matches occur in the text or all matches are replaced. The match may occur anywhere within the text - if you wish to "anchor" this, use "\^" at the start of the regex and/or "$" at the end of the regex. When the regular expression does not match the given string then the same string is returned.

For example: HTTP.RES.BODY(999).REGEX_REPLACE(re!\\bpassword:\\s*\\b!, "password: ***", ALL) will replace all occurrences of "password:" with "password: ***" This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

regex- Regular Expression

replacement- String to replace the match

mode- Mode of replacement

`Returns:` text_t

`*REGEX_SELECT` (`re` regex)

The REGEX_SELECT operator in this object overrides the Text REGEX_SELECT operator to operate on all the instances of the current header type. Selects the Text that matches the input regular expression in any instance of the header value. The order in which the header instances will be matched is from the last to the first.

For example: HTTP.REQ.HEADER("via").REGEX_SELECT(re!NS-CACHE-\\d\\.\\d:\\s*\\d{1,3}!) will select "NS-CACHE-7.0: 70" This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

regex- Regular Expression

`Returns:` text_t

`*REPEAT` (`uint` i)

Produces a string which contains 'i' sequential copies of the input string.

`Parameters``:`

i- the number of times to repeat the string (0 or more)

`Returns:` text_t

`*REPLACE_ALL_VALUES` (text_t value)

Replaces all the values in each name-value pair with the specified string argument. For example, given argument string "?" the list 'a=b,c=d,e=f' will result in the name-value list 'a=?,c=?,e=?'. Quotes will be stripped from the values being replaced. Empty values will be replaced with the value provided. Empty elements will be preserved.

`Parameters` (expressions not allowed) `:`

value- value to replace existing values

`Returns:` nvlist_t

`*SET_CHAR_SET` (charset_e charset)

Set the character set to use for subsequent functions that use text.

`Parameters` (expressions not allowed) `:`

charset- Character Set

`Returns:` http_cookie_t

`*SET_TEXT_MODE` (textmode_e mode)

The mode setting of a Text object controls the behavior of many Text operations. The Text mode settings may also control the behavior of some operations in objects (like List) that build upon the Text object. IGNORECASE, NOIGNORECASE - controls whether string comparison is case sensitive or not. URLENCODED - If set then all Text operations are carried out after translating all %HH or %uHHHH encodings in the underlying byte stream. 1. %HH will be translated to the character Y where HH denotes the ascii value of character Y in hexadecimal. For example, the encoded text "http%3a/.html" will be decoded to "http:/.html" 2. %uWWHH will be translated to the character sequence YZ where WW denotes the ascii value of character Y in hexadecimal and HH denotes the ascii value of character Z in hexadecimal. For example, the encoded text "http%u3a2f.html" and "http%u003a/.html" will both be decoded to"http:/.html" NOURLENCODED - Indicates that no percent encodings are present in the Text object. No percent decoding will be performed on the Text object. PLUS_AS_SPACE - If set then all Text operations are carried out after converting occurrences of the plus character to whitespace. For example, the text "hello+world" will be decoded to "hello world" NO_PLUS_AS_SPACE - If set, then the plus

character will not be converted to whitespace in the Text object. BACKSLASH_ENCODED - If set, then all Text operations are carried out after performing the following operations: 1. \\XXX will be translated to the character Y where XXX denotes the ascii value of character Y in octal. The valid range of octal values for this type of encoding is \\0 to \\377. For example, the encoded text "http\ \72/.html" and "http\\072/.html" will both be decoded to "http:/.html" 2. \\xHH will be translated to the character Y where HH denotes the ascii value of character Y in hexadecimal. For example, the encoded text "http\\x3a/.html" will be decoded to "http:/.html" 3. \\\\uWWXX will be translated to the character sequence YZ where WW denotes the ascii value of character Y in hexadecimal and XX denotes the ascii value of character Z in hexadecimal. For example, the encoded text "http%u3a2f.html" and "http%u003a/.html" will both be decoded to"http:/.html" 4. Occurences of "\ \b", "\\n", "\\t", "\\f" and "\\r" are translated to the corresponding ascii characters. NO_BACKSLASH_ENCODED - If set, then backslash decoding will not be performed on the Text object. BAD_ENCODE_RAISE_UNDEF - If set, then UNDEF is raised if either the URLENCODED or BACKSLASH_ENCODED mode is set and a bad encoding corresponding to the specified encoding mode is encountered. NO_BAD_ENCODE_RAISE_UNDEF - If set, then UNDEF will not be raised when a bad encoding is encountered in the Text object. The Text operations operate on characters (as opposed to operating on bytes). By default a single byte represents a character using the ASCII encoding. But if URLENCODED mode is set then 3 bytes may represent a character. A PREFIX(3) operation will select the first 3 characters in the Text object. That means it may select up to 9 bytes for URLENCODED Text object. In the case of multibyte decodings as a result of %uXXXX or \\\\uXXXX, Text operations which attempt to treat the multiple decoded bytes as distinct characters are not allowed.

`Parameters` (expressions not allowed) `:`

mode- Text Mode

`Returns:` http_cookie_t

`*SKIP` (`char` c, `uint` i)

Select the Text after skipping over a prefix of the current Text. The skipped over prefix is the longest prefix that has at most Count (2nd argument) occurrences of character in the 1st argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

c- Character

i- Count

`Returns:` text_t

`*SKIP` (`uint` i)

Select the Text after skipping over a prefix in the current Text. The length of the prefix is equal to the number in the argument. If there aren't enough characters in the Text object then the entire Text is skipped over.

`Parameters` (expressions not allowed) `:`

i- Prefix Length

`Returns:` text_t

`*STARTSWITH_ANY` (text_t patset_name)

Results in Boolean TRUE value if the Text starts with any of the strings that are bound to the patset or dataset named by the string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` bool_at

`*STARTSWITH_INDEX` (text_t patset_name)

Returns the numerical index of the matching string, if the Text starts with any of the strings that are bound to the patset or dataset named by the string argument. Returns 0 if there is no match. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` num_at

`*STARTSWITH` (text_t start)

Results in Boolean TRUE value if a prefix of the Text object matches the string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

start- String

`Returns:` bool_at

`*STRIP_CHARS` (text_t s)

From the selected text remove the characters specified in the string.

For example: Say the selected text is / "foo.xyz=bar" /. Then on executing STRIP_CHARS('.=') or STRIP_CHARS('..=') the selected text will become /fooxyzbar /. Note that repeating character has same effect as it would be if it present only once. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*STRIP_END_CHARS` (text_t s)

Selects the Text after stripping off characters in the end of the current Text object.

For example: Say the selected text is / "foo.xyz=bar" /. Then on executing STRIP_END_CHARS('ar') the selected text will become /foo.xyz=b /. Note that repeating character has same effect as it would be if it present only once. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*STRIP_END_WS`

Selects the Text after stripping off white space in the end of the current Text object.

`Returns:` text_t

`*STRIP_START_CHARS` (text_t s)

Selects the Text after stripping off characters in the beginning of the current Text object.

For example: Say the selected text is / "foo.xyz=bar" /. Then on executing STRIP_START_CHARS('of') the selected text will become /.xyz=bar /. Note that repeating character has same effect as it would be if it present only once. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*STRIP_START_WS`

Selects the Text after stripping off white space in the beginning of the current Text object.

`Returns:` text_t

`*SUBSTR_ANY` (text_t patset_name)

Select any one sub-string that matches any string in the given patset or dataset. The patset cannot have strings longer than 255 characters. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` text_t

`*SUBSTR` (`uint` start, `uint` len)

Select the Text object of the given length at the given offset. Offset it 0 based. If there aren't enough characters after the offset then all the remaining characters are selected.

`Parameters``:`

start- Offset

len- Length

`Returns:` text_t

`*SUBSTR` (text_t s)

The SUBSTR operator in this object overrides the Text SUBSTR operator to operate on all the instances of the current header type. Selects Text that matches the input string argument. The order in which the instances of the header are matched is from the last instance to the first.

HTTP/1.1 200 OK\\r\\n MyHdr: 111abc\\r\\n Content-Length: 200\\r\\n MyHdr: 111def\\r\\n \\r\\n

For example: HTTP.RES.HEADER("MyHdr").SUBSTR("111") selects "111" in the last instance of MyHdr, the one with value "111def". This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*SUFFIX` (`char` c, `uint` i)

Select a suffix of the Text. The selected suffix is the longest possible suffix containing at most Count (2nd arg) occurrences of the character in the 1st argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

c- Character

i- Count

`Returns:` text_t

`*SUFFIX` (`uint` i)

Select a suffix of the Text. The length of the suffix is equal to the number in the argument. If there aren't enough characters in the Text object then the entire Text is selected.

`Parameters``:`

i- Suffix Length

`Returns:` text_t

`*TO_LOWER`

Converts the selected text to lower case.

For example, the string "ABCd" is converted to "abcd"

`Returns:` text_t

`*TO_UPPER`

Converts the selected text to upper case.

For example, the string "abcD" is converted to "ABCD"

`Returns:` text_t

`*TRUNCATE` (`char` c, `uint` i)

Select the Text after truncating a suffix from the current Text object. The truncated suffix is the longest possible suffix containing at most Count (2nd arg) occurrences of the character in the 1st argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

c- Character

i- Count

`Returns:` text_t

`*TRUNCATE` (`uint` i)

Select the Text after truncating a suffix of the Text. The length of the suffix truncated is equal to the number in the argument. If there aren't enough characters in the Text then then all the characters are truncated.

`Parameters``:`

i- Suffix Length

`Returns:` text_t

`*TYPECAST_AVP_T`

Convert text_t to avp_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (avp_t : Operations that can be performed on the returned AVPs.

`Note:` An AVP can have multiple instances in a Diameter message. However, the system can access only the first 16 instances.

`Example:`

- To get the first value of AVP code 266 from a request, use: DIAMETER.REQ.AVP(266).VALUE(0).
- To get the fourth value of AVP code 266 from a request, use: DIAMETER.REQ.AVP(266).VALUE(3).
- To check if AVP code 1000 in the response has the vendor-specific bit set, use: DIAMETER.RES.AVP(1000).IS_VENDOR_SPECIFIC.

)

`Returns:` avp_t

`*TYPECAST_AVP_UNUM_T`

Convert text_t to avp_unum_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (avp_unum_t : In Diameter AVP based expressions can be written as DIAMETER.REQ.AVP(<avpcode>). For example Auth-Application-Id AVP (AVP code 258) can be extracted as DIAMETER.REQ.AVP(258) For few of the important AVPs we provide aliases. For example this AVP based expression can also be written as DIAMETER.REQ.AUTH_APPLICATION_ID. This expression returns either a object of class avp_t or returns a numerical value (object of class unsigned_long_at). The numerical value for this object is derived from the value in first instance of the AVP.)

`Returns:` avp_unum_t

`*TYPECAST_BOOL_AT`

Convert text_t to bool_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (bool_at : Boolean Operations)

`Returns:` bool_at

`*TYPECAST_COOKIE_T`

Convert text_t to cookie_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (cookie_t : The HTTP Cookie type provides operations for a cookie as it appears in the Set-Cookie and Set-Cookie2 header. In this type the Name-Value List operations are also available. The first delimiter is = and the element delimiter is ;. Multiple consecutive ; are treated as one. (Same as applying the method IGNORE_EMPTY_ELEMENTS on a Name-Value List.) You can use the Name-value List operations to access cookie attributes.

The name comparison for all list operations is case insensitive. In this type Text operations are also available. Each cookie begins with a COOKIE_NAME=COOKIE_VALUE pair followed by zero or more semi-colon separated attribute-value pairs. If an attribute appears more than once in a cookie, the value associated with the first appearance of the attribute is returned.

Format Cookie: Cookie1=Value;Version=decimal;Value;Domain=Value;Path=Value)

`Returns:` cookie_t

`*TYPECAST_DIAMETER_FLAG_T`

Convert text_t to diameter_flag_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (diameter_flag_t : Provides operation to treat the underlying 1 byte as set of bit flags. then set/unset/test/reset_all operations can be done on flag)

`Returns:` diameter_flag_t

`*TYPECAST_DNS_DOMAINNAME_T`

Convert text_t to dns_domainname_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (dns_domainname_t : This object provides operations for parsing the DNS domain name as it appears at various places in the DNS data. The format is abc.foo.com.)

`Returns:` dns_domainname_t

`*TYPECAST_DNS_FLAG_T`

Convert text_t to dns_flag_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (dns_flag_t : Provides operations to test/set/unset a flag in dns header.)

`Returns:` dns_flag_t

`*TYPECAST_DOUBLE_AT`

Convert text_t to double_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_at : Double Value)

`Returns:` double_at

`*TYPECAST_DOUBLE_T` (double_format_e format)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error.)

`Parameters` (expressions not allowed) `:`

format- Format

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, double_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, ip_address_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, num_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, time_local_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, time_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, unsigned_long_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_HTTP_CACHE_CONTROL_T`

Convert text_t to http_cache_control_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_cache_control_t : This object provides for the ability to work on HTTP Cache-Control headers. The name comparison for all list operations is case insensitive.)

`Returns:` http_cache_control_t

`*TYPECAST_HTTP_CONTENT_LENGTH_T`

Convert text_t to http_content_length_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_content_length_t : The HTTP.REQ.CONTENT_LENGTH or HTTP.RES.CONTENT_LENGTH object can be treated as a HTTP Header or as a Number. The numerical value for this object is derived from the value in the last instance of the Content-Length header.)

`Returns:` http_content_length_t

`*TYPECAST_HTTP_COOKIE_T`

Convert text_t to http_cookie_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_cookie_t : This object provides operations for parsing the HTTP cookie header. The name-value pair is derived from the value in the last instance of Cookie header. The format is Cookie : name0=value0; name1=value1; An HTTP Cookie header can have multiple occurrences. COUNT will return a Number containing how many headers of the current type exist. The name comparison for all list operations is case insensitive. The system does not keep track of more than 15 HTTP headers. The result will be undefined if there are more than 15 instances of the header.)

`Returns:` http_cookie_t

`*TYPECAST_HTTP_DATE_T`

Convert text_t to http_date_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_date_t : The HTTP.REQ.DATE or HTTP.RES.DATE object can be treated as a HTTP header or a Time object. The Time value is derived from the value in the last instance of the Date header. The date formats supported are RFC 822 (updated by RFC 1123), RFC 1036 (obsoletes RFC850) and ANSI C asctime() formats.)

`Returns:` http_date_t

`*TYPECAST_HTTP_HEADER_T` (text_t name)

Convert text_t to http_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_header_t : When typecasting a Text object to HTTP Header a header name must be provided.For example: HTTP.REQ.HEADER("MyHdr").TYPECAST_HTTP_HEADER_T("InHdr"))

`Parameters` (expressions not allowed) `:`

name- Header Name

`Returns:` http_header_t

`*TYPECAST_HTTP_HOSTNAME_T`

Convert text_t to http_hostname_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_hostname_t : This object provides operations for parsing the HTTP hostname as it appears at various places in the HTTP protocol data. The format is abc.foo.com:8080.)

`Returns:` http_hostname_t

`*TYPECAST_HTTP_METHOD_T`

Convert text_t to http_method_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_method_t : This object provides Text operations and HTTP Request Method Enum operations on the HTTP request method.)

`Returns:` http_method_t

`*TYPECAST_HTTP_SET_COOKIE_T`

Convert text_t to http_set_cookie_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_set_cookie_t : HTTP.RES.SET_COOKIE provides operations for parsing and operating on the SET-COOKIE header that is present in the HTTP response. HTTP Set-Cookie header supports Text and HTTP Header operations. For most Text operations the value in the last Set-Cookie header is selected. HTTP Set-Cookie header also supports special operations to extract cookies from the response. It is assumed that there will be only one cookie in a Set-Cookie header.)

`Returns:` http_set_cookie_t

`*TYPECAST_HTTP_URL_T`

Convert text_t to http_url_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_url_t : HTTP.REQ.URL provides operations for parsing and operating on the URL that is present in the first line of the HTTP request header. The supported format is \[<protocol>://<hostname>\]<path>?<query>. The Text object backing a HTTP URL object has the Text Mode set to URLENCODED by default.)

`Returns:` http_url_t

`*TYPECAST_HTTP_VERSION_T`

Convert text_t to http_version_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_version_t : HTTP.REQ.VERSION or HTTP.RES.VERSION provide operations to extract HTTP version information.)

`Returns:` http_version_t

`*TYPECAST_IPV6_ADDRESS_AT`

Convert text_t to ipv6_address_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ipv6_address_at : Provides operations for the 128-bit IPv6 address value. Some general information regarding IPv6 expressions: IPv6 PIXL expressions can be combined with other PIXL expressions using the '+' operator. The output is expected to be the concatenation of the string representations of the individual PIXL expressions. No other operator other than '+' is expected to work when any of the operands is an IPv6 PIXL expression. Also, IPv6 PIXL expressions can be combined with any other type of PIXL expression except a PIXL expression that produces a bool result. In other words, if A and/or B are two IPv6 addresses, A+B should result in the string AB. When one of A or B is an IPv6 address, the other can only be a number or a string and not a boolean. Further, when A and/or B is an IPv6 address, the only operator allowed between them is '+'.

Example: Let the client source IPv6 address be ABCD:1234::ABCD. Let the server destination IPv4 address be 10.100.10.100. Then the expression CLIENT.IPV6.SRC + SERVER.IP.DST should produce the output "ABCD:1234::ABCD10.100.10.100". Similarly, CLIENT.IPV6.SRC + 5 should produce the result ABCD:1234::ABCD5)

`Returns:` ipv6_address_at

`*TYPECAST_IPV6_ADDRESS_T`

Convert text_t to ipv6_address_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ipv6_address_t : This object represents an IPv6 address present in the 1000:1001:CD10:0000:0000:89AB:4567:CDEF format.)

`Returns:` ipv6_address_t

`*TYPECAST_IPV6_SUBNET_AT`

Convert text_t to ipv6_subnet_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ipv6_subnet_at : Provides operations for the integral IPv6 subnet address value.)

`Returns:` ipv6_subnet_at

`*TYPECAST_IPV6_SUBNET_T`

Convert text_t to ipv6_subnet_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ipv6_subnet_t : This object represents an IPv6 subnet address present in the 1000:1001:CD10:0000:0000:89AB:4567:CDEF/64 format.)

`Returns:` ipv6_subnet_t

`*TYPECAST_IP_ADDRESS_AT`

Convert text_t to ip_address_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ip_address_at : Provides operations for the 32-bit integral IP address value.)

`Returns:` ip_address_at

`*TYPECAST_IP_ADDRESS_T`

Convert text_t to ip_address_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ip_address_t : Represents an IP address present in the 10.100.200.1 format.)

`Returns:` ip_address_t

`*TYPECAST_IP_OPTIONS_T`

Convert text_t to ip_options_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ip_options_t : IP protocol options)

`Returns:` ip_options_t

`*TYPECAST_IP_OPTIONS_TYPE_T`

Convert text_t to ip_options_type_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ip_options_type_t : IP Options Type)

`Returns:` ip_options_type_t

`*TYPECAST_IP_TOS_T`

Convert text_t to ip_tos_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ip_tos_t : Provides operations to TOS field in IP header.)

`Returns:` ip_tos_t

`*TYPECAST_LIST_T` (`char` sep)

Convert text_t to list_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (list_t : The character separator has to be provided when typecasting a textual context to list type. The current text mode has no effect on the character separator. For example if the current text mode is IGNORECASE and the separator is p then P will not be treated as a separator.)

`Parameters` (expressions not allowed) `:`

sep- Separator

`Returns:` list_t

`*TYPECAST_MAC_ADDRESS_AT`

Convert text_t to mac_address_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (mac_address_at : Provides operations for the 48-bit MAC address value.)

`Returns:` mac_address_at

`*TYPECAST_MAC_ADDRESS_T`

Convert text_t to mac_address_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (mac_address_t : Represents a MAC address present in the 12:34:56:78:9a:bc format.)

`Returns:` mac_address_t

`*TYPECAST_NUM_AT`

Convert text_t to num_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (num_at : Number Value)

`Returns:` num_at

`*TYPECAST_NUM_T` (num_format_e format)

Convert text_t to num_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (num_t : Treat the underlying text as a Number in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error.)

`Parameters` (expressions not allowed) `:`

format- Format

`Returns:` num_t

`*TYPECAST_NUM_T` (num_format_e format, num_at default_value)

Convert text_t to num_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (num_t : Treat the underlying text as a Number in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` num_t

`*TYPECAST_NVLIST_T` (`char` sep1, `char` sep2)

Convert text_t to nvlist_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (nvlist_t : Two character delimiters have to be provided when typecasting a Text object to a Name-Value List. The first delimited separates the name from the value. The second delimiter separates list items. For example typecast_nvlist_t('=', '&') handles a

URL query string. The Text Mode has no effect on the character delimiters. For example if the current text mode is IGNORECASE and a delimiter is p then P will not be treated as a delimiter.)

`Parameters` (expressions not allowed) `:`

sep1- delimiter1

sep2- delimiter2

`Returns:` nvlist_t

`*TYPECAST_NVLIST_T` (`char` sep1, `char` sep2, `char` quote)

Convert text_t to nvlist_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (nvlist_t : Two character delimiters and quote-character have to be provided when typecasting a Text object to a Name-Value List that supports quote-character. The first delimited separates the name from the value. The second delimiter separates list items. The third value specifies the quote character. For example typecast_nvlist_t('=', ';', "") handles a name-value list separated by semi-colons that allows quoting. The quote-character specifies that the value can occur within the quotes and the delimiters within the quote-characters should not be taken into account. The Text Mode has no effect on the character delimiters. For example if the current text mode is IGNORECASE and a delimiter is p then P will not be treated as a delimiter.)

`Parameters` (expressions not allowed) `:`

sep1- delimiter1

sep2- delimiter2

quote- quote-character.

`Returns:` nvlist_t

`*TYPECAST_PROTOCOL_BUFFER_T`

Convert text_t to protocol_buffer_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (protocol_buffer_t : gRPC Protocol Buffers interface)

`Returns:` protocol_buffer_t

`*TYPECAST_RADIUS_AVP_T`

Convert text_t to radius_avp_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (radius_avp_t : Operations that can be performed on the returned AVPs.

`Note:` An AVP can have multiple instances in a radius message. However, the system can access only the first 16 instances.

`Example:`

- To get the first value of AVP code 26 from a request, use: radius.REQ.AVP(26).VALUE(0).
- To get the fourth value of AVP code 26 from a request, use: radius.REQ.AVP(26).VALUE(3).

)

`Returns:` radius_avp_t

`*TYPECAST_RADIUS_AVP_VALUE_T`

Convert text_t to radius_avp_value_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (radius_avp_value_t : Provides operations to typecast RADIUS AVP value to Integer value or IP Address.)

`Returns:` radius_avp_value_t

`*TYPECAST_SEQ_TEXT_T`

Convert text_t to seq_text_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (seq_text_t : Represents the Text Sequence class.)

`Returns:` seq_text_t

`*TYPECAST_SERVICEPATH_T`

Convert text_t to servicepath_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (servicepath_t : Operations that can be performed on the service path.

`Example:`

- To get the name of the service path applicable to current subscriber, use: SUBSCRIBER.SERVICEPATH
- To determine If the service function is the next in the service path applicable to scubscriber, use: SUBSCRIBER.SERVICEPATH.IS_NEXT().

)

`Returns:` servicepath_t

`*TYPECAST_SIP_CALLID_HEADER_T`

Convert text_t to sip_callid_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_callid_header_t : This object provides operations for parsing the SIP callid header.)

`Returns:` sip_callid_header_t

`*TYPECAST_SIP_CONTENT_LENGTH_T`

Convert text_t to sip_content_length_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_content_length_t : The SIP.REQ.CONTENT_LENGTH or SIP.RES.CONTENT_LENGTH object can be treated as a SIP Header or as a Number. The numerical value for this object is derived from the value in the last instance of the Content-Length header.)

`Returns:` sip_content_length_t

`*TYPECAST_SIP_FROM_HEADER_T`

Convert text_t to sip_from_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_from_header_t : This object provides operations for parsing the SIP From header.)

`Returns:` sip_from_header_t

`*TYPECAST_SIP_HEADER_T` (text_t name)

Convert text_t to sip_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_header_t : When typecasting a Text object to SIP Header a header name must be provided.For example: SIP.REQ.HEADER("MyHdr").TYPECAST_SIP_HEADER_T("InHdr"))

`Parameters` (expressions not allowed) `:`

name- Header Name

`Returns:` sip_header_t

`*TYPECAST_SIP_HOSTNAME_T`

Convert text_t to sip_hostname_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_hostname_t : This object provides operations for parsing the SIP hostname as it appears at various places in the SIP protocol data. The format is abc.foo.com:5060.)

`Returns:` sip_hostname_t

`*TYPECAST_SIP_METHOD_T`

Convert text_t to sip_method_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_method_t : This object provides Text operations and SIP Request Method Enum operations on the SIP request method.)

`Returns:` sip_method_t

`*TYPECAST_SIP_TO_HEADER_T`

Convert text_t to sip_to_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_to_header_t : This object provides operations for parsing the SIP From header.)

`Returns:` sip_to_header_t

`*TYPECAST_SIP_URL_T`

Convert text_t to sip_url_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_url_t : SIP.REQ.URL provides operations for parsing and operating on the URL that is present in the first line of the SIP request header. The supported format is \[<protocol>://<hostname>\]<path>?<query>. The Text object backing a SIP URL object has the Text Mode set to URLENCODED by default.)

`Returns:` sip_url_t

`*TYPECAST_SIP_VERSION_T`

Convert text_t to sip_version_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_version_t : SIP.REQ.VERSION or SIP.RES.VERSION provide operations to extract SIP version information.)

`Returns:` sip_version_t

`*TYPECAST_SIP_VIA_HEADER_T`

Convert text_t to sip_via_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_via_header_t : This object provides operations for parsing the SIP Via header.)

`Returns:` sip_via_header_t

`*TYPECAST_SSLVPN_MODE_T`

Convert text_t to sslvpn_mode_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sslvpn_mode_t : This object provides Text operations and SSLVPN Mode Enum operations on the SSLVPN request method.)

`Returns:` sslvpn_mode_t

`*TYPECAST_SSL_TEXT_T` (text_t name)

Convert text_t to ssl_text_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ssl_text_t : Treat the underlying text object as SSL Text.)

`Parameters` (expressions not allowed) `:`

name- Name

`Returns:` ssl_text_t

`*TYPECAST_TCP_OPTIONS_T`

Convert text_t to tcp_options_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (tcp_options_t : TCP Protocol Options)

`Returns:` tcp_options_t

`*TYPECAST_TCP_OPTIONS_TYPE_T`

Convert text_t to tcp_options_type_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (tcp_options_type_t : TCP Protocol Options Type)

`Returns:` tcp_options_type_t

`*TYPECAST_TCP_REPEATER_OPTION_T`

Convert text_t to tcp_repeater_option_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (tcp_repeater_option_t : TCP Protocol Option : Repeater)

`Returns:` tcp_repeater_option_t

`*TYPECAST_TEXT_T`

Convert http_header_t to text_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (text_t : Designates any piece of text.)

`Returns:` text_t

`*TYPECAST_TIME_AT`

Convert text_t to time_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (time_at : Treats a number value as number of seconds since GMT Jan 1 1970 0h 0m 0s.)

`Returns:` time_at

`*TYPECAST_TIME_LOCAL_AT`

Convert text_t to time_local_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (time_local_at : Treats a number value as number of seconds since GMT Jan 1 1970 0h 0m 0s as adjsuted for the local time zone.)

`Returns:` time_local_at

`*TYPECAST_TIME_T`

Convert text_t to time_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (time_t : This object treats a Text object as a date string. The formats supported are

1\. RFC822 :: Sun, 06 Nov 1994 08:49:37 GMT 2\. RFC850 :: Sunday, 06-Nov-94 08:49:37 GMT 3\. ASCTIME :: Sun Nov 6 08:49:37 1994 4\. ASCTIME like :: Sun Nov 6 08:49:37 1994 5\. ASCTIME like :: Sun Nov 06 08:49:37 1994 6\. Http Set-Cookie Expiry date :: Sun, 06-Nov-1994 08:49:37 GMT)

`Returns:` time_t

`*TYPECAST_UNSIGNED_LONG_AT`

Convert text_t to unsigned_long_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_at : Unsigned Long(64bit) Value)

`Returns:` unsigned_long_at

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error.)

`Parameters` (expressions not allowed) `:`

format- Format

`Returns:` unsigned_long_t

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format, ip_address_at default_value)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` unsigned_long_t

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format, unsigned_long_at default_value)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX,

DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` unsigned_long_t

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format, num_at default_value)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` unsigned_long_t

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format, time_local_at default_value)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one

or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` unsigned_long_t

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format, time_at default_value)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` unsigned_long_t

`*TYPECAST_UNUM_TEXT_T`

Convert text_t to unum_text_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unum_text_t : Provides operations to treat the underlying OctectString as Binary String or unsigned long value .)

`Returns:` unum_text_t

`*TYPECAST_URL_CATEGORY_T`

Convert text_t to url_category_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (url_category_t : Retrieves URL category and attributes from an URL)

`Returns:` url_category_t

`*TYPECAST_VENDOR_SPEC_APPID_AVP_T`

Convert text_t to vendor_spec_appid_avp_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (vendor_spec_appid_avp_t : Retrieves AVPs that are nested in the grouped AVP Vendor-Specific-Application-Id (code 260). The nested AVPs are:

- Vendor-Id
- Auth-Application-Id
- Acct-Application-Id

For example, to retrieve the Auth-Application-Id AVP from the Vendor-Specific-Application-Id AVP:

- For requests: DIAMETER.REQ.VENDOR_SPECIFIC_APPLICATION_ID.AUTH_APPLICATION_ID
- For responses: DIAMETER.RES.VENDOR_SPECIFIC_APPLICATION_ID.AUTH_APPLICATION_ID

)

`Returns:` vendor_spec_appid_avp_t

`*TYPECAST_VENDOR_SPEC_RADIUS_AVP_T`

Convert text_t to vendor_spec_radius_avp_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (vendor_spec_radius_avp_t :

- Vendor-Id

To retrieve the Vendor-Id from the Vendor-Specific AVP:

- RADIUS.REQ.VENDOR_SPECIFIC.VENDORID

)

`Returns:` vendor_spec_radius_avp_t

`*UNQUOTE` (`char` c)

If selected text is quoted by character c, Remove character c from beginning and end.

For example: Say the selected text is / "foo xyz bar " /. Then on executing UNQUOTE("") the selected text will become /foo xyz bar / This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

c- Character

`Returns:` text_t

`*URLSET_MATCHES_ANY` (text_t urlset_name)

Results in Boolean TRUE value if and only if the Text matches any of the patterns that are specified in the urlset named by the string argument. The matching is case-insensitive for domains, but case-sensitive for paths. For example:

- HTTP.REQ.HOST.APPEND(HTTP.REQ.URL).URLSET_MATCHES_ANY("urlset_forbidden") returns true when the combined domain and URL matches any pattern in the urlset whose name is "urlset_forbidden".

`Parameters` (expressions not allowed) `:`

urlset_name- urlset name

`Returns:` bool_at

`*URL_CATEGORIZE` (`uint` min_reputation, `uint` max_reputation)

Returns the URL category for the supplied URL with the given minimum and maximum reputation score. Where a score of 5 is most risky and 1 is least risky. If either score is set to 0, that bound would be ignored. By specifying the reputation scores, the function will returned the category with the highest score (most risky) based on the bounds. If there was an error getting the category or if the URL is invalid then it will result in an Undef error. For example: HTTP.REQ.HOST.APPEND(HTTP.REQ.URL).URL_CATEGORIZE(0, 0) returns value when the combined domain and URL is looked up for the URL category with the highest reputation score (most risky).

`Parameters` (expressions not allowed) `:`

min_reputation- Minimum reputation score of URL category

max_reputation- Maximum reputation score of URL category

`Returns:` url_category_t

`*URL_RESERVED_CHARS_SAFE`

Converts URL reserved characters to corresponding '%XX' values and retains the rest. This is a read only operation.

```
Based on RFC3986, following are considered URL unreserved characters:

    Alpha-numeric characters: a-z, A-Z, 0-9

    Hyphen and underscore: "-", "_"

    Dot: "."

    Tilde: "~"
```

The rest are converted to %XX encoding, 'XX' is the hex-based representation of the input character. If the requirement is to encode all but URL safe characters, please consider using HTTP_URL_SAFE method.

`Returns:` text_t

`*VALUES`

Extracts a list of only the values from the name-value pair list. For example the list 'a=b,c=d,e=f' will result in the list 'b,d,f'. Note that lists do not honor the quote characters, so any nvlist_at entry that has quotes and a quoted entry includes a separator will be split at that embedded separator. Quote characters will not be stripped from the values. Empty elements and empty values will be ignored.

`Returns:` list_t

`*VALUE` (`uint` i)

Operate as Text on the value component of the specified name-value component in the list. The index of the name-value component given by the argument is 0-based. If the specified index is greater than the number of components then a zero length Text object is produced.

`Parameters` (expressions not allowed) `:`

i- Index

`Returns:` text_t

`*VALUE` (text_t name)

Operate as Text on the value component of the specified name-value component in the list. The name-value component is specified by the argument by providing the name whose value is needed. The first component that matches the name is selected. The matching process honors the IGNORECASE and the NOIGNORECASE text modes. The URLENCODED and the NOURLENCODED text modes are ignored.

`Parameters` (expressions not allowed) `:`

name- Name

`Returns:` text_t

`*VALUE` (text_t name, `uint` i)

Operate as Text on the value component of the specified name-value component in the list. The name-value component is specified by the argument by providing the name whose value is needed. In a name-value list the same name can be repeated multiple times. The Index argument controls which occurence of the matching name-value component should be selected. The Index is 0-based. If the Index is too big then the Text object that is produced will have zero length. The matching process honors the IGNORECASE and the NOIGNORECASE text modes. The URLENCODED and the NOURLENCODED text modes are ignored.

`Parameters` (expressions not allowed) `:`

name- Name

i- Index

`Returns:` text_t

`*XML_DECRYPT` (text_t certKeyName)

Decrypt the selected content, which was encrypted using the W3C XML Encryption standard.

`Parameters` (expressions not allowed) `:`

certKeyName- identifies the certkey object containing the RSA private key to be used to decrypt the bulk encryption key in the selected EncryptedData element.

`Returns:` text_t

`*XML_ENCRYPT` (text_t certKeyName, encrypt_method_e method)

Encrypt the selected cleartext using the W3C XML Encryption standard.

`Parameters` (expressions not allowed) `:`

certKeyName- identifies the certkey object containing an X.509 certificate with the RSA public key to be used to encrypt the generated bulk encryption key. Note that the certKey object need not, and usually will not, include the associated RSA private key.

method- specifies the bulk encryption method (rc4, des3, aes128, aes192, or aes256) used to encrypt the content.

`Returns:` text_t

`*XML_ENCRYPT` (text_t certKeyName, encrypt_method_e method, `uint` flags)

Encrypt the selected cleartext using the W3C XML Encryption standard.

`Parameters` (expressions not allowed) `:`

certKeyName- identifies the certkey object containing an X.509 certificate with the RSA public key to be used to encrypt the generated bulk encryption key. Note that the certKey object need not, and usually will not, include the associated RSA private key.

method- specifies the bulk encryption method (rc4, des3, aes128, aes192, or aes256) used to encrypt the content.

flags- optional bit mask to specify optional elements in the EncryptedData element. These are hints to tell the receiver what private key to use to decrypt the bulk encryption key, providing information from the certKey's X.509 certificate.

- 1 - include a KeyName element with the certKeyName;
- 2 - include a KeyValue element with the RSA public key from the certificate;
- 4 - include an X509IssuerSerial element with the certificate serial number and issuer DN;
- 8 - include an X509SubjectName element with the certificate subject DN;
- 16 - include an X509Certificate element with the entire certificate;

`Returns:` text_t

`*XPATH_HTML_WITH_MARKUP` (`xpath_str` xpathex)

Applies an XPath expression to the DOM for an HTML document and returns the selected node-set or string, including markup like element tags. node-sets are converted to strings using the standard

XPath string conversion routine. The selected portion of the document can be used as the target for rewrite actions.

Examples: HTTP.REQ.BODY(1000).XPATH_HTML_WITH_MARKUP(xp%//md/head/title%) returns the <title> element in the document's <head> This can be used in a rewrite action to replace or delete the <title> element.

`Parameters` (expressions not allowed) `:`

xpathex- XPath Expression

`Returns:` text_t

`*XPATH_HTML` (`xpath_bool` xpathex)

Applies an XPath expression to the DOM for an HTML document and a boolean value.

Examples: HTTP.RES.BODY(1000).XPATH_HTML(xp%boolean(/md/head/meta)%) returns true if the <meta> element exists as a child of <head> element.

`Parameters` (expressions not allowed) `:`

xpathex- XPath Expression

`Returns:` bool_at

`*XPATH_HTML` (`xpath_double` xpathex)

Applies an XPath expression to the DOM for an HTML document and a double value.

Examples: HTTP.RES.BODY(1000).XPATH_HTML(xp%number(//video/@height)%) returns the numeric value of the height attribute of the first <video> element.

`Parameters` (expressions not allowed) `:`

xpathex- XPath Expression

`Returns:` double_at

`*XPATH_HTML` (`xpath_str` xpathex)

Applies an XPath expression to the DOM for an HTML document and returns the selected node-set or string. node-sets are converted to strings using the standard XPath string conversion routine.

Examples: HTTP.REQ.BODY(1000).XPATH_HTML(xp%//img/@src%) returns the string value of the src attribute of the first

HTTP_DATE_T

The HTTP.REQ.DATE or HTTP.RES.DATE object can be treated as a HTTP header or a Time object. The Time value is derived from the value in the last instance of the Date header. The date formats supported are RFC 822 (updated by RFC 1123), RFC 1036 (obsoletes RFC850) and ANSI C asctime() formats.

This topic lists the expressions that are provided by this class.

`*Note` *: Expressions with the * symbol are inherited / promoted from http_header_t time_at

- `TYPECAST_HTTP_HEADER_T`

  Convert http_date_t to http_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_header_t : Typecast an HTTP Header object of a specific type to HTTP Header.For example: HTTP.REQ.CONTENT_LENGTH.TYPECAST_HTTP_HEADER_T)

`Returns:` http_header_t

`*TYPECAST_NUM_AT`

Convert http_date_t to num_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (num_at : Number Value)

`Returns:` num_at

`*TYPECAST_TIME_AT`

Convert http_date_t to time_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (time_at : Treats a number value as number of seconds since GMT Jan 1 1970 0h 0m 0s.)

`Returns:` time_at

`*ABS`

Return the absolute value of the number.

`Returns:` num_at

`*ADD` (double_at i)

Return the Double Value after adding the argument to the current double value.

`Parameters``:`

i- Double

`Returns:` double_at

`*ADD` (ip_address_at i)

Return the Unsigned Long after adding the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*ADD` (unsigned_long_at i)

Return the Unsigned Long after adding the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*ADD` (num_at i)

Return the Number Value after adding the argument to the current number value.

`Parameters``:`

i- Number

`Returns:` num_at

`*ADD` (time_local_at i)

Return the Unsigned Long after adding the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*ADD` (time_at i)

Return the Unsigned Long after adding the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*AFTER_REGEX` (`re` regex)

The AFTER_REGEX operator in this object overrides the Text AFTER_REGEX operator to operate on all the instances of the current header type. Selects the Text after the text that matches the input regular expression in any instance of the header value. The order in which the header instances will be matched is from the last to the first.

For example: HTTP.REQ.HEADER("etag").AFTER_REGEX(re/KX/) will select "DAPPER" from "KXDAPPER". This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed)`:`

regex- Regular Expression

`Returns:` text_t

`*AFTER_STR_ANY` (text_t patset_name)

Selects the Text that is present after the first occurrence of any of the strings that are bound to the patset named by the string argument. If there is no match to any of the strings bound to the patset in the current Text object then the result Text object has 0 length. The patset cannot have strings longer than 255 characters. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed)`:`

patset_name- Pattern Set Name

`Returns:` text_t

`*AFTER_STR` (text_t s)

The AFTER_STR operator in this object overrides the Text AFTER_STR operator to operate on all the instances of the current header type. Selects Text after the first occurrence of the input string argument. The order in which the instances of the header are matched is from the last instance to the first.

HTTP/1.1 200 OK\\r\\n MyHdr: 111abc\\r\\n Content-Length: 200\\r\\n MyHdr: 111def\\r\\n \\r\\n

Examples: HTTP.RES.HEADER("MyHdr").AFTER_STR("111") selects "def" in the last instance of MyHdr, the one with value "111def". HTTP.RES.HEADER("MyHdr").AFTER_STR("1ab") selects "c" in the first instance of MyHdr, the one with value "abc111". This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*APPEND` (bool_at b)

Appends the given boolean's string representation to the current string.

`Parameters``:`

b- the boolean value to append.

`Returns:` text_t

`*APPEND` (double_at i)

Appends the given double's string representation to the current string.

`Parameters``:`

i- the double value to append.

`Returns:` text_t

`*APPEND` (ip_address_at addr)

Appends the given IPv4's string representation to the current string.

`Parameters``:`

addr- the IPv4 address to append.

`Returns:` text_t

`*APPEND` (num_at i)

Appends the given number's string representation to the current string.

`Parameters``:`

i- the number value to append.

`Returns:` text_t

`*APPEND` (time_local_at t)

Appends the given time's string representation to the current string.

`Parameters``:`

t- the time value to append.

`Returns:` text_t

`*APPEND` (time_at t)

Appends the given time's string representation to the current string.

`Parameters``:`

t- the time value to append.

`Returns:` text_t

`*APPEND` (unsigned_long_at i)

Appends the given unsigned long's string representation to the current string.

`Parameters``:`

i- the unsigned long value to append.

`Returns:` text_t

`*APPEND` (ipv6_address_at addr)

Appends the given IPv6's string representation to the current string.

`Parameters``:`

addr- the IPv6 address to append.

`Returns:` text_t

`*APPEND` (ipv6_subnet_at addr)

Appends the given IPv6 subnet's string representation to the current string.

`Parameters``:`

addr- the IPv6 subnet to append.

`Returns:` text_t

`*APPEND` (mac_address_at addr)

Appends the given MAC's string representation to the current string.

`Parameters``:`

addr- the MAC address to append.

`Returns:` text_t

`*APPEND` (text_t str)

Appends the given string to the string representation of the current time value.

`Parameters``:`

str- the string to append.

`Returns:` text_t

`*APPEND` (time_at t)

Appends the given time's string representation to the current string.

`Parameters``:`

t- the time value to append.

`Returns:` text_t

`*AS_MICROSEC_STR`

Returns the current system time in the following format Format: Wday, day Month year hh:mm:ss.ffffff GMT ffffff represents microseconds Examples:

Mon, 05 Mar 2018 10:23:36.568419 GMT

`Returns:` text_t

`*AS_MILLISEC_STR`

Returns the current system time in the following format Format: Wday, day Month year hh:mm:ss.fff GMT fff represents milliseconds Examples:

Mon, 05 Mar 2018 10:23:36.568 GMT

`Returns:` text_t

`*AS_NANOSEC_STR`

Returns the current system time in the following format Format: Wday, day Month year hh:mm:ss.fffffffff GMT fffffffff represents nanoseconds Accuracy may be at larger granularity than nanosecond resolution. Examples:

Mon, 05 Mar 2018 10:23:36.568419567 GMT

`Returns:` text_t

`*B64DECODE`

Decodes the selected text using base64 decoding.

For example, the string "TWFu" is converted to "Man"

`Returns:` text_t

`*B64ENCODE`

Encodes the selected text using base64 encoding.

For example, the string "Man" is converted to "TWFu"

`Returns:` text_t

`*BEFORE_REGEX` (`re` regex)

The BEFORE_REGEX operator in this object overrides the Text BEFORE_REGEX operator to operate on all the instances of the current header type. Selects the Text before the text that matches the input regular expression in any instance of the header value. The order in which the header instances will be matched is from the last to the first.

For example: HTTP.RES.HEADER("content-type").BEFORE_REGEX(re#/#) will select "text" from "text/plain". This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

regex- Regular Expression

`Returns:` text_t

`*BEFORE_STR_ANY` (text_t patset_name)

Selects the Text that is present before the first occurrence of any of the strings that are bound to the patset or datasetnamed by the string argument. If there is no match to any of the strings bound to the patset in the current Text object then the result Text object has 0 length. The patset cannot have strings longer than 255 characters. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` text_t

`*BEFORE_STR` (text_t s)

The BEFORE_STR operator in this object overrides the Text BEFORE_STR operator to operate on all the instances of the current header type. Selects Text before the first occurrence of the input string argument. The order in which the instances of the header are matched is from the last instance to the first.

HTTP/1.1 200 OK\\r\\n MyHdr: abc111\\r\\n Content-Length: 200\\r\\n MyHdr: def111\\r\\n \\r\\n

Examples: HTTP.RES.HEADER("MyHdr").BEFORE_STR("111") selects "def" in the last instance of MyHdr, the one with value "def111". HTTP.RES.HEADER("MyHdr").BEFORE_STR("bc1") selects "a" in the first instance of MyHdr, the one with value "abc111". This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*BETWEEN` (double_at i, double_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (double_at i, ip_address_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (double_at i, unsigned_long_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (ip_address_at i, double_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (ip_address_at i, ip_address_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (ip_address_at i, unsigned_long_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (unsigned_long_at i, double_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (unsigned_long_at i, ip_address_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (unsigned_long_at i, unsigned_long_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (double_at i, num_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (ip_address_at i, num_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (unsigned_long_at i, num_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (double_at i, time_local_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (ip_address_at i, time_local_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (unsigned_long_at i, time_local_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (double_at i, time_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (ip_address_at i, time_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (unsigned_long_at i, time_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (num_at i, double_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (num_at i, ip_address_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (num_at i, unsigned_long_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (num_at i, num_at j)

Returns Boolean TRUE if the number value is greater than or equal to the Lower argument and the number value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (num_at i, time_local_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (num_at i, time_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (text_t start, text_t end)

Results in Boolean TRUE value if length of the Text object is greater than or equal to the sum of the Start and End argument lengths and if the prefix of the Text object matches the Start string argument and if the Suffix of the Text object matches the End string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

start- Start

end- End

`Returns:` bool_at

`*BETWEEN` (time_at time1, time_at time2)

Results in a Boolean TRUE value if the time value is between the Lower and the Upper time arguments. Both the Lower and the Upper time arguments must be fully specified.

For example - GMT 1995 Jan is fully specified. But GMT Jan or GMT 1995 20 or GMT Jan Mon_2 are not fully specified. The Upper and Lower arguments must be both GMT or both Local. The day of the week must not be present in either the Lower or the Upper argument. It is OK to specify the day of the month as the 1st, 2nd, 3rd or 4th weekday of the month (example Wed_3 is the 3rd Wednesday of the month). The Upper Time argument must be bigger than the Lower Time argument.

Assume the current time value is GMT 2005 May 1 10h 15m 30s. This is the 1st Sunday of the month of May in 2005. BETWEEN(GMT 2004, GMT 2006): TRUE BETWEEN(GMT 2004 Jan, GMT 2006 Nov): TRUE BETWEEN(GMT 2004 Jan, GMT 2006): TRUE BETWEEN(GMT 2005 May Sun_1, GMT 2005 May Sun_3): TRUE BETWEEN(GMT 2005 May 1, GMT May 2005 1): TRUE BETWEEN(LOCAL 2005 May 1, LOCAL May 2005 1): Answer depends on the NetScaler system's timezone.

`Parameters` (expressions not allowed) `:`

time1- Lower Time

time2- Upper Time

`Returns:` bool_at

`*BETWEEN` (time_local_at i, double_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (time_local_at i, ip_address_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (time_local_at i, unsigned_long_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (time_local_at i, num_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (time_local_at i, time_local_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (time_local_at i, time_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (time_at i, double_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (time_at i, ip_address_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (time_at i, unsigned_long_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (time_at i, num_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (time_at i, time_local_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (time_at time1, time_at time2)

Returns Boolean TRUE if the time value is greater than or equal to the Lower argument and the time value is lesser than or equal to the Upper argument.

`Parameters``:`

time1- Lower GMT Time Value

time2- Upper GMT Time Value

`Returns:` bool_at

`*BIN_DECODE` (binary_encoding_e encoding)

Decode the encoded input into its original byte sequence. An incorrectly enooded input will result in an Undef error.

`Parameters` (expressions not allowed) `:`

encoding- specifies how the bytes are encoded.

`Returns:` text_t

`*BIN_ENCODE` (binary_encoding_e encoding)

Encode the input byte sequence. Note that BIN_ENCODE(hex_colons) is equivalent to BLOB_TO_HEX().

`Parameters` (expressions not allowed) `:`

encoding- specifies how the bytes are to be encoded.

`Returns:` text_t

`*BITAND` (ip_address_at i)

Return the Unsigned Long Value after bitwise ANDing the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*BITAND` (unsigned_long_at i)

Return the Unsigned Long Value after bitwise ANDing the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*BITAND` (num_at i)

Return the Number Value after bitwise ANDing the argument to the current number value.

`Parameters``:`

i- Number

`Returns:` num_at

`*BITAND` (time_local_at i)

Return the Unsigned Long Value after bitwise ANDing the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*BITAND` (time_at i)

Return the Unsigned Long Value after bitwise ANDing the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*BITNEG`

Return the Number Value after bitwise negating the current number value.

`Returns:` num_at

`*BITOR` (ip_address_at i)

Return the Unsigned Long Value after bitwise ORing the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*BITOR` (unsigned_long_at i)

Return the Unsigned Long Value after bitwise ORing the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*BITOR` (num_at i)

Return the Number Value after bitwise ORing the argument to the current number value.

`Parameters``:`

i- Number

`Returns:` num_at

`*BITOR` (time_local_at i)

Return the Unsigned Long Value after bitwise ORing the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*BITOR` (time_at i)

Return the Unsigned Long Value after bitwise ORing the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*BITXOR` (ip_address_at i)

Return the Unsigned Long Value after bitwise XORing the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*BITXOR` (unsigned_long_at i)

Return the Unsigned Long Value after bitwise XORing the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*BITXOR` (num_at i)

Return the Number Value after bitwise XORing the argument to the current number value.

`Parameters``:`

i- Number

`Returns:` num_at

`*BITXOR` (time_local_at i)

Return the Unsigned Long Value after bitwise XORing the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*BITXOR` (time_at i)

Return the Unsigned Long Value after bitwise XORing the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*BLOB_TO_HEX`

Convert to hexadecimal representation and select text.

For example, the byte string abc is converted to 61:62:63.

`Returns:` text_t

`*COMPARE` (text_t s)

Results in a Number Value which is the result of comparison of the input argument with the Text object. The result is greater than 0 if the Text object is lexicographically greater than the argument. The result is 0 if the Text object and the argument match. The result is less than 0 if the Text object is lexicographically lesser than the argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` num_at

`*CONTAINS_ANY` (text_t patclass_name)

The CONTAINS_ANY in this object overrides the Text CONTAINS_ANY operator to operate on all the instances of the current header type. Returns Boolean TRUE if any of the patterns associated with input patclass is present in any instance of the header value. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patclass_name- Patclass Name

`Returns:` bool_at

`*CONTAINS_INDEX` (text_t patclass_name)

The CONTAINS_INDEX in this object overrides the Text CONTAINS_INDEX operator to operate on all the instances of the current header type. Returns the index of the matching pattern associated with input patclass that is present in any instance of the header value. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patclass_name- Patclass Name

`Returns:` num_at

`*CONTAINS` (text_t s)

The CONTAINS in this object overrides the Text CONTAINS operator to operate on all the instances of the current header type. Returns Boolean TRUE if the input Pattern String is present in any instance of the header value.

GET / HTTP/1.1\\r\\n Host: abc.com\\r\\n MyHdr: abc\\r\\n Content-Length: 200\\r\\n MyHdr: def\\r\\n

HTTP/1.1 200 OK\\r\\n MyHdr: abc\\r\\n Content-Length: 200\\r\\n MyHdr: def\\r\\n \\r\\n

Examples: HTTP.RES.HEADER("MyHdr").CONTAINS("de") is TRUE.
HTTP.RES.HEADER("MyHdr").CONTAINS("bcd") is FALSE.
HTTP.REQ.HEADER("MyHdr").CONTAINS("de") is TRUE.
HTTP.REQ.HEADER("MyHdr").CONTAINS("bcd") is FALSE. The system does not concatenate the different values. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- Pattern String

`Returns:` bool_at

`*COUNT`

An HTTP header can have multiple occurrences. COUNT will return a Number containing how many headers of the current type exist.

HTTP/1.1 200 OK\\r\\n MyHdr: abc\\r\\n Content-Length: 200\\r\\n MyHdr: def\\r\\n \\r\\n

For example: HTTP.RES.HEADER("MyHdr").COUNT will return Number 2. The system does not keep track of more than 15 HTTP headers. The result will be undefined if there are more than 15 instances of the header.

`Returns:` num_at

`*CRC32`

Returns a 32-bit integer computed by applying a CRC (cyclic redundancy check) function to the selected text. This is the CRC function used by Ethernet, MPEG-2, PKZIP, GZIP, PNG, and many other applications. For example, the expression to compute the CRC value of the (first 1000 bytes of the) body of an HTTP request is: HTTP.REQ.BODY(1000).CRC32

`Returns:` num_at

`*DAY`

Extracts the day of the month from the current system time, and returns that value as a number from 1 through 31 representing that day.

`Returns:` num_at

`*DECODE_USING_TEXT_MODE`

Decodes the selected text using the currently configured text encoding methods like URLENCODED, BACKSLASH_ENCODED, PLUS_AS_SPACE, NOURLENCODED, NO_BACKSLASH_ENCODED and NO_PLUS_AS_SPACE. Text encoding methods are set using SET_TEXT_MODE method.

`Returns:` text_t

`*DECRYPT`

Decrypt the selected base64-encoded ciphertext using the configured encryptionParams.

`Returns:` text_t

`*DECRYPT` (binary_encoding_e in_encoding)

Decrypt the selected ciphertext using the configured encryptionParams.

`Parameters` (expressions not allowed) `:`

in_encoding- specifies how the input ciphertext is encoded. If the ciphertext is not encoded as specified, causes an Undef error.

`Returns:` text_t

`*DECRYPT` (text_t encryptionKey)

Decrypt the selected base64-encoded encrypted bytes using the configured encryption key.

`Parameters` (expressions not allowed) `:`

encryptionKey- identifies the encryptionKey object to provide the cipher method, mode, padding, key, encrypted format and optional initialization vector (IV).

`Returns:` text_t

`*DECRYPT` (text_t encryptionKey, binary_encoding_e in_encoding)

Decrypt the selected base64-encoded encrypted bytes using the configured encryption key.

`Parameters` (expressions not allowed) `:`

encryptionKey- identifies the encryptionKey object to provide the cipher method, mode, padding, key, encrypted format, and optional initialization vector (IV).

in_encoding- specifies how the input ciphertext is encoded. If the ciphertext is not encoded as specified, causes an Undef error.

`Returns:` text_t

`*DIGEST` (digest_method_e method)

Returns a byte sequence computed by applying the the specified message digest method to the selected text.

`Parameters` (expressions not allowed) `:`

method- digest method to apply to the input text

`Returns:` text_t

`*DIV` (double_at i)

Return the Double Value after dividing the current double value by the argument.

`Parameters``:`

i- Double

`Returns:` double_at

`*DIV` (ip_address_at i)

Return the Unsigned Long Value after dividing the current unsigned long value by the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*DIV` (unsigned_long_at i)

Return the Unsigned Long Value after dividing the current unsigned long value by the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*DIV` (num_at i)

Return the Number Value after dividing the current number value by the argument.

`Parameters``:`

i- Number

`Returns:` num_at

`*DIV` (time_local_at i)

Return the Unsigned Long Value after dividing the current unsigned long value by the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*DIV` (time_at i)

Return the Unsigned Long Value after dividing the current unsigned long value by the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*ENCRYPT`

Encrypt the selected plaintext bytes using the configured encryptionParams. The resulting ciphertext is base64-encoded.

`Returns:` text_t

`*ENCRYPT` (binary_encoding_e out_encoding)

Encrypt the selected plaintext bytes using the configured encryptionParams.

`Parameters` (expressions not allowed) `:`

out_encoding- specifies how the resulting ciphertext is encoded.

`Returns:` text_t

`*ENCRYPT` (text_t encryptionKey)

Encrypt the selected cleartext bytes using the configured encryption key.

`Parameters` (expressions not allowed) `:`

encryptionKey- identifies the encryptionKey object to provide the cipher method, mode, padding, key, encrypted format and optional initialization vector (IV).

`Returns:` text_t

`*ENCRYPT` (text_t encryptionKey, binary_encoding_e out_encoding)

Encrypt the selected cleartext bytes using the configured encryption key.

`Parameters` (expressions not allowed) `:`

encryptionKey- identifies the encryptionKey object to provide the cipher method, mode, padding, key, encrypted format and optional initialization vector (IV).

out_encoding- specifies how the resulting ciphertext is encoded.

`Returns:` text_t

`*ENDSWITH_ANY` (text_t patset_name)

Results in Boolean TRUE value if the Text ends with any of the strings that are bound to the patset or dataset named by the string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` bool_at

`*ENDSWITH_INDEX` (text_t patset_name)

Returns the numerical index of the matching string, if the Text ends with any of the strings that are bound to the patset or dataset named by the string argument. Returns 0 if there is no match. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` num_at

`*ENDSWITH` (text_t end)

Results in Boolean TRUE value if a suffix of the Text object matches the string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

end- String

`Returns:` bool_at

`*EQUALS_ANY` (text_t patset_name)

The EQUALS_ANY in this object overrides the Text EQUALS_ANY operator to operate on all the instances of the current header type. Returns Boolean TRUE if any of the patterns associated with input patset is equal to any instance of the header value. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Patset Name

`Returns:` bool_at

`*EQUALS_INDEX` (text_t patset_name)

The EQUALS_INDEX in this object overrides the Text EQUALS_INDEX operator to operate on all the instances of the current header type. Returns the index of the matching pattern associated with input patset is equal to any instance of the header value. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Patset Name

`Returns:` num_at

`*EQ` (double_at i)

Returns Boolean TRUE if the double value is equal to the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`*EQ` (ip_address_at i)

Returns Boolean TRUE if the unsigned long is equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*EQ` (unsigned_long_at i)

Returns Boolean TRUE if the unsigned long is equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*EQ` (num_at i)

Returns Boolean TRUE if the number value is equal to the argument.

`Parameters``:`

i- Number

`Returns:` bool_at

`*EQ` (text_t s)

Results in Boolean TRUE value if the Text object matches the input argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*EQ` (time_at t)

Results in Boolean TRUE value if the time value is equal to the argument time.

Assume the current time value is GMT 2005 May 1 10h 15m 30s. This is the 1st Sunday of the month of May in 2005.

EQ(GMT 2005): TRUE EQ(GMT 2005 Dec): FALSE EQ(Local 2005 May): TRUE or FALSE depending on the current timezone. EQ(GMT 10h): TRUE EQ(GMT 10h 30s): TRUE EQ(GMT May 10h): TRUE EQ(GMT Sun): TRUE EQ(GMT May Sun_1): TRUE

`Parameters` (expressions not allowed)`:`

t- Time

`Returns:` bool_at

`*EQ` (time_local_at i)

Returns Boolean TRUE if the unsigned long is equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*EQ` (time_at t)

Results in Boolean TRUE value if the time value is equal to the argument GMT time value.

`Parameters``:`

t- GMT Time Value

`Returns:` bool_at

`*EXISTS`

Returns TRUE if an instance of the current header type exists.

`Returns:` bool_at

`*GET_SIGNED16` (`uint` n, endian_e endianness)

Get the 16-bit signed binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

endianness- Select little or big endian

`Returns:` num_at

`*GET_SIGNED32` (`uint` n, endian_e endianness)

Get the 32-bit signed binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

endianness- Select little or big endian

`Returns:` num_at

`*GET_SIGNED8` (`uint` n)

Get the 8-bit signed binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

`Returns:` num_at

`*GET_UNSIGNED16` (`uint` n, endian_e endianness)

Get the 16-bit unsigned binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

endianness- Select little or big endian

`Returns:` num_at

`*GET_UNSIGNED32` (`uint` n, endian_e endianness)

Get the 32-bit unsigned binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

endianness- Select little or big endian

`Returns:` unsigned_long_at

`*GET_UNSIGNED64` (`uint` n, endian_e endianness)

Get the 64-bit unsigned binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

endianness- Select little or big endian

`Returns:` unsigned_long_at

`*GET_UNSIGNED8` (`uint` n)

Get the 8-bit unsigned binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

`Returns:` num_at

`*GET_URLSET_METADATA` (text_t urlset_name)

Returns metadata value corresponding to pattern in the urlset. The matching is case-insensitive for domains, but case-sensitive for paths. If no pattern is matched within the urlset, the return value is a NULL string. For example:

- HTTP.REQ.HOST.APPEND(HTTP.REQ.URL).GET_URLSET_METADATA("urlset_forbidden") returns value when the combined domain and URL is looked up in the urlset whose name is "urlset_forbidden".

`Parameters` (expressions not allowed) `:`

urlset_name- urlset name

`Returns:` text_t

`*GE` (double_at i)

Returns Boolean TRUE if the double value is greater than or equal to the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`*GE` (ip_address_at i)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*GE` (unsigned_long_at i)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*GE` (num_at i)

Returns Boolean TRUE if the number value is greater than or equal to the argument.

`Parameters``:`

i- Number

`Returns:` bool_at

`*GE` (text_t s)

Results in Boolean TRUE value if the Text object is greater than or equal to the input argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*GE` (time_at t)

Results in Boolean TRUE value if the time value is greater than or equal to the argument time.

Assume the current time value is GMT 2005 May 1 10h 15m 30s. This is the 1st Sunday of the month of May in 2005.

GE(GMT 2004): TRUE GE(GMT 2005 Jan): TRUE GE(Local 2005 May): TRUE or FALSE depending on the current timezone. GE(GMT 8h): TRUE GE(GMT 30m): FALSE GE(GMT May 10h): TRUE GE(GMT May 10h 0m): TRUE GE(GMT Sun): TRUE GE(GMT May Sun_1): TRUE

`Parameters` (expressions not allowed)`:`

t- Time

`Returns:` bool_at

`*GE` (time_local_at i)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*GE` (time_at t)

Results in Boolean TRUE value if the time value is greater than or equal to the argument GMT time value.

`Parameters``:`

t- GMT Time Value

`Returns:` bool_at

`*GRPC`

Interprets a text_t string as a Protocol Buffer (protocol_buffer_t type). Example: HTTP.REQ.BODY(1000).GRPC.STRING(1).EQ("bookname")

`Returns:` protocol_buffer_t

`*GT` (double_at i)

Returns Boolean TRUE if the double value is greater than the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`*GT` (ip_address_at i)

Returns Boolean TRUE if the unsigned long value is greater than the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*GT` (unsigned_long_at i)

Returns Boolean TRUE if the unsigned long value is greater than the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*GT` (num_at i)

Returns Boolean TRUE if the number value is greater than the argument.

`Parameters``:`

i- Number

`Returns:` bool_at

`*GT` (text_t s)

Results in Boolean TRUE value if the Text object is greater than the input argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*GT` (time_at t)

Results in Boolean TRUE value if the time value is greater than the argument time.

Assume the current time value is GMT 2005 May 1 10h 15m 30s. This is the 1st Sunday of the month of May in 2005.

GT(GMT 2004): TRUE GT(GMT 2005 Jan): TRUE GT(Local 2005 May): TRUE or FALSE depending on the current timezone. GT(GMT 8h): TRUE GT(GMT 30m): FALSE GT(GMT May 10h): FALSE GT(GMT May 10h 0m): TRUE GT(GMT Sun): FALSE GT(GMT May Sun_1): FALSE

`Parameters` (expressions not allowed) `:`

t- Time

`Returns:` bool_at

`*GT` (time_local_at i)

Returns Boolean TRUE if the unsigned long value is greater than the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*GT` (time_at t)

Results in Boolean TRUE value if the time value is greater than the argument GMT time value.

`Parameters``:`

t- GMT Time Value

`Returns:` bool_at

`*HASH`

Returns a positive 31 bit integer value computed by applying a proprietary NetScaler hash function to the selected text. This function is not case- sensitive and ignores whitespaces. For example, applying the HASH function to two strings "Ab c" and "abc" would produce the same value. This function should not be used for security purposes; use instead the DIGEST function with one of the standard digest methods.

`Returns:` num_at

`*HMAC` (text_t hmacKey)

Returns a byte sequence computed by applying the HMAC (Hash Message Authenticastion Code) function to the selected text using the configured HMAC key.

`Parameters` (expressions not allowed) `:`

hmacKey- indentifies the hmacKey object to provide the digest (hash) method and the key.

`Returns:` text_t

`*HMAC` (text_t hmacKey, binary_encoding_e out_encoding)

Returns a byte sequence computed by applying the HMAC (Hash Message Authenticastion Code) function to the selected text using the configured HMAC key .

`Parameters` (expressions not allowed) `:`

hmacKey- indentifies the hmacKey object to provide the digest (hash) method and the key.

out_encoding- specifies how the resulting HMAC is encoded.

`Returns:` text_t

`*HOURS`

Extracts the hour from the current system time, and returns that value as an integer from 0 to 23.

`Returns:` num_at

`*HTML_XML_SAFE`

Apply XML safe transform and select text.

Converts '<', '>' and '&' in the input text to '<', '>' and '&' respectively; other characters in the input are not modified. This transform safeguards against XSS based attacks. This is a read only operation.

`Returns:` text_t

`*HTTP_HEADER_SAFE`

Apply Header safe transform and select text. Converts all new line ('\\n') characters present in the input text to '%0A' so that they can safely be used in HTTP headers. This transform safeguards against response-splitting attacks. This is a read only operation.

`Returns:` text_t

`*HTTP_URL_SAFE`

Apply URL safe transform and select text. Converts URL unsafe characters to corresponding '%xx' values and retains the rest. This is a read only operation.

Based on RFC2396, following are considered URL safe characters:

Alpha-numeric characters: a-z, A-Z, 0-9

Hyphen and underscore: "-", "_"

Dot: "."

Exclamation mark: "!"

Tilde: "~"

Asterix: "*"

Single quote: "'"

Open and close parentheses: "(", ")"

Semi-colon: ";"

Colon: ":"

At symbol: "@"

Question mark: "?"

Equals: "="

Dollar: "$"

Percent: "%"

Ampersand: "&"

Plus: "+"

Comma: ","

Forward slash: ".html"

The rest are converted to %XX encoding, 'XX' is the hex-based representation of the input character. If the requirement is to encode all but URL unreserved characters, please consider using URL_RESERVED_CHARS_SAFE method.

`Returns:` text_t

`*INSTANCE` (`uint` lineno)

An HTTP header can have multiple occurrences. INSTANCE(0) will select the last header line of the current type, INSTANCE(1) will select the last but one header line and so on. The counting goes backward. Only the last 15 instances of a header are accessible. Therefore Instance Number cannot be greater than 14.

HTTP/1.1 200 OK\\r\\n MyHdr: abc\\r\\n Content-Length: 200\\r\\n MyHdr: def\\r\\n \\r\\n

For example: HTTP.RES.HEADER("MyHdr").INSTANCE(1) will return a Text object referring to "MyHdr: abc\\r\\n". It can not be used in HTTP response processing contexts.

`Parameters` (expressions not allowed) `:`

lineno- Instance Number

`Returns:` text_t

`*IS_BOOL_AT`

Results in Boolean TRUE value if the Text is of boolean type.

`Returns:` bool_at

`*IS_DOUBLE_AT`

Results in Boolean TRUE value if the Text is of double data type.

`Returns:` bool_at

`*IS_IPV6_AT`

Results in Boolean TRUE value if the Text is of IPv6 data type.

`Returns:` bool_at

`*IS_IPV6_SUBNET_AT`

Results in Boolean TRUE value if the Text is of IPv6 subnet data type.

`Returns:` bool_at

`*IS_IP_AT`

Results in Boolean TRUE value if the Text is of IPv4 data type.

`Returns:` bool_at

`*IS_MAC_ADDRESS_AT`

Results in Boolean TRUE value if the Text is of mac address data type.

`Returns:` bool_at

`*IS_NUM_AT`

Results in Boolean TRUE value if the Text is of number type.

`Returns:` bool_at

`*IS_NUM_AT` (num_format_e format)

Results in Boolean TRUE value if the Text is of number type with given input base.

`Parameters` (expressions not allowed) `:`

format- number format

`Returns:` bool_at

`*IS_STRINGMAP_KEY` (text_t string_map_name)

Returns true if the string that it operates on is present in the string map. Text mode IGNORECASE, NOIGNORECASE - controls whether key lookup in string map is case sensitive or not. For example:

- HTTP.REQ.URL.IS_STRINGMAP_KEY("url_stringmap") returns true if value of HTTP.REQ.URL is present as key in the string map whose name is "url_stringmap".
- HTTP.REQ.URL.SET_TEXT_MODE(IGNORECASE). IS_STRINGMAP_KEY("url_stringmap") returns true if value of HTTP.REQ.URL is present as key in the string map whose name is "url_stringmap". Key lookup in this case is done case-insensitively.

`Parameters` (expressions not allowed) `:`

string_map_name- identifies the string map.

`Returns:` bool_at

`*IS_TIME_AT`

Results in Boolean TRUE if the Text follows any of the standard time formats given below, otherwise false. Tue, 05 Nov 1994 08:12:31 GMT RFC822 Tuesday, 05-Nov-94 08:12:31 GMT RFC850 Tue Nov 4 08:12:31 1994 asctime

`Returns:` bool_at

`*IS_UNSIGNED_LONG_AT`

Results in Boolean TRUE value if the Text is of unsigned long data type.

`Returns:` bool_at

`*IS_UNSIGNED_LONG_AT` (num_format_e format)

Results in Boolean TRUE value if the Text is of unsigned long data type with given input base.

`Parameters` (expressions not allowed) `:`

format- number format

`Returns:` bool_at

`*JWT_VERIFY_CERTKEY` (text_t certkey_name)

Verifies the signature on the input JSON Web Token (JWT), using the RSA public key in the X.509 certificate in the specified certkey object. The token has the format HEADER.PAYLOAD.SIGNATURE where

- HEADER is a base64-encoded JSON structure indicating a signature algorithm and token type, e.g.'{"alg":"RS256","typ":"JWT"}'
- PAYLOAD is a base64-encoded JSON structure with asserted claims, e.g. '{"loggedInAs":"admin","iat":1422779638}'
- SIGNATURE is the base64-encoded bytes for the signature on HEADER.PAYLOAD.

Returns true if the signature is verified for the header and payload using the specified public key; false if the signature is not verified

`Parameters``:`

certkey_name- identifies the certkey object containing an X.509 certificate holding the RSA public key. Results in an Undef error if the certkey object does not exist or does not contain an X.509 certificate with an RSA public key, if the token is not correctly formatted, or if the verification operation cannot complete.

`Returns:` bool_at

`*JWT_VERIFY_XML` (text_t xml_pkey)

Verifies the signature on the input JSON Web Token (JWT), using the RSA public key supplied by the specified XML element. The token has the format HEADER.PAYLOAD.SIGNATURE where

- HEADER is a base64-encoded JSON structure indicating a signature algorithm and token type, e.g.'{"alg":"RS256","typ":"JWT"}'
- PAYLOAD is a base64-encoded JSON structure with asserted claims, e.g. '{"loggedInAs":"admin","iat":1422779638}'
- SIGNATURE is the base64-encoded bytes for the signature on HEADER.PAYLOAD.

Returns true if the signature is verified for the header and payload using the specified public key; false if the signature is not verified

`Parameters``:`

xml_pkey- an expression that supplies an <RSAKeyValue> element with the public key. Results in an Undef error if the XML element is invalid or does not correctly specify an RSA public key, if the token is not correctly formatted, or if the verification operation cannot complete.

`Returns:` bool_at

`*LENGTH`

Results in a Number Value that is the number of characters (not bytes) in the Text object.

`Returns:` num_at

`*LE` (double_at i)

Returns Boolean TRUE if the double value is lesser than or equal to the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`*LE` (ip_address_at i)

Returns Boolean TRUE if the unsigned long value is lesser than or equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*LE` (unsigned_long_at i)

Returns Boolean TRUE if the unsigned long value is lesser than or equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*LE` (num_at i)

Returns Boolean TRUE if the number value is lesser than or equal to the argument.

`Parameters``:`

i- Number

`Returns:` bool_at

`*LE` (text_t s)

Results in Boolean TRUE value if the Text object is less than or equal to the input argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*LE` (time_at t)

Results in Boolean TRUE value if the time value is lesser than or equal to the argument time.

Assume the current time value is GMT 2005 May 1 10h 15m 30s. This is the 1st Sunday of the month of May in 2005.

LE(GMT 2006): TRUE LE(GMT 2005 Dec): TRUE LE(Local 2005 May): TRUE or FALSE depending on the current timezone. LE(GMT 8h): FALSE LE(GMT 30m): TRUE LE(GMT May 10h): TRUE LE(GMT Jun 11h): TRUE LE(GMT Wed): TRUE LE(GMT May Sun_1): TRUE

`Parameters` (expressions not allowed) `:`

t- Time

`Returns:` bool_at

`*LE` (time_local_at i)

Returns Boolean TRUE if the unsigned long value is lesser than or equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*LE` (time_at t)

Results in Boolean TRUE value if the time value is less than or equal to the argument GMT time value.

`Parameters``:`

t- GMT Time Value

`Returns:` bool_at

`*LOCATION_LONG`

Get the location qualifier from CLIENT.IP.SRC.LOCATION.GET(n) (ISO short name) and then convert it to human readable long name. This conversion is valid only for country names. Correct Country qualifier value (number) in GET(n) is left up to the user as qualifiers are user configurable. Expression example: CLIENT.IP.SRC.LOCATION.GET(1).LOCATION_LONG For example: Data from each expression CLIENT.IP.SRC.LOCATION: NA.US.California.SantaClara.*.* CLIENT.IP.SRC.LOCATION.GET(1): US CLIENT.IP.SRC.LOCATION.GET(1).LOCATION_LONG: United States

`Returns:` text_t

`*LSHIFT` (`uint` i)

Return the Number Value after bitwise left shifting the current number value by the argument number of bits. Note that the number of bits shifted is i modulo 32. For example, let HTTP.REQ.URL.LENGTH be 4. Then, HTTP.REQ.URL.LENGTH.LSHIFT(1) = HTTP.REQ.URL.LENGTH.LSHIFT(33) = 8, since 33 on division by 32 yields a remainder of 1.

`Parameters``:`

i- Left Shift Length

`Returns:` num_at

`*LT` (double_at i)

Returns Boolean TRUE if the double value is lesser than the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`*LT` (ip_address_at i)

Returns Boolean TRUE if the unsigned long value is lesser than the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*LT` (unsigned_long_at i)

Returns Boolean TRUE if the unsigned long value is lesser than the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*LT` (num_at i)

Returns Boolean TRUE if the number value is lesser than the argument.

`Parameters``:`

i- Number

`Returns:` bool_at

`*LT` (text_t s)

Results in Boolean TRUE value if the Text object is less than the input argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*LT` (time_at t)

Results in Boolean TRUE value if the time value is lesser than the argument time.

Assume the current time value is GMT 2005 May 1 10h 15m 30s. This is the 1st Sunday of the month of May in 2005.

LT(GMT 2006): TRUE LT(GMT 2005 Dec): TRUE LT(Local 2005 May): TRUE or FALSE depending on the current timezone. LT(GMT 8h): FALSE LT(GMT 30m): TRUE LT(GMT May 10h): FALSE LT(GMT Jun 11h): TRUE LT(GMT Wed): TRUE LT(GMT May Sun_1): FALSE

`Parameters` (expressions not allowed)`:`

t- Time

`Returns:` bool_at

`*LT` (time_local_at i)

Returns Boolean TRUE if the unsigned long value is lesser than the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*LT` (time_at t)

Results in Boolean TRUE value if the time value is less than the argument GMT time value.

`Parameters``:`

t- GMT Time Value

`Returns:` bool_at

`*MAP_STRING_DEFAULT_TO_KEY` (text_t string_map_name)

Returns the value corresponding to the key in the string map. This is similar to the MAP_STRING method, but if the key is not present then instead of returning a null string, it returns the key itself. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

string_map_name- identifies the string map.

`Returns:` text_t

`*MAP_STRING` (text_t string_map_name)

Returns value corresponding to key in the string map. Key is the string that it is given as input. Text mode IGNORECASE, NOIGNORECASE - controls whether key lookup in string map is case sensitive or not. For example:

- HTTP.REQ.URL.MAP_STRING("url_stringmap") returns value when the value of HTTP.REQ.URL is used as key in the string map whose name is "url_stringmap".
- HTTP.REQ.URL.SET_TEXT_MODE(IGNORECASE). MAP_STRING("url_stringmap") returns value when the value of HTTP.REQ.URL is used as key in the string map whose name is "url_stringmap". Key lookup in this case is done case-insensitively.

`Parameters` (expressions not allowed) `:`

string_map_name- identifies the string map.

`Returns:` text_t

`*MARK_SAFE`

Mark the PIXL expression safe without applying any safe transform.

`Returns:` text_t

`*MAX` (double_at i)

Return the maximum double value after comparing the argument with the current double value.

`Parameters``:`

i- Double

`Returns:` double_at

`*MAX` (ip_address_at i)

Return the maximum unsigned long value after comparing the argument value to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MAX` (unsigned_long_at i)

Return the maximum unsigned long value after comparing the argument value to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MAX` (num_at i)

Return the maximum value after comparing the argument with the current number value.

`Parameters``:`

i- Number

`Returns:` num_at

`*MAX` (text_t s)

Compares the string argument with the current string and returns the max string. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*MAX` (time_local_at i)

Return the maximum unsigned long value after comparing the argument value to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MAX` (time_at i)

Return the maximum unsigned long value after comparing the argument value to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MINUTES`

Extracts the minute from the current system time, and returns that value as an integer from 0 to 59.

`Returns:` num_at

`*MIN` (double_at i)

Return the minimum double value after comparing the argument with the current double value.

`Parameters``:`

i- Double

`Returns:` double_at

`*MIN` (ip_address_at i)

Return the minimum unsigned long value after comparing the argument value to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MIN` (unsigned_long_at i)

Return the minimum unsigned long value after comparing the argument value to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MIN` (num_at i)

Return the minimum value after comparing the argument with the current number value.

`Parameters``:`

i- Number

`Returns:` num_at

`*MIN` (text_t s)

Compares the string argument with the current string and returns the min string. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*MIN` (time_local_at i)

Return the minimum unsigned long value after comparing the argument value to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MIN` (time_at i)

Return the minimum unsigned long value after comparing the argument value to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MOD` (ip_address_at i)

Return the Unsigned Long Value that is the renaminder after dividing the current unsigned long value by the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MOD` (unsigned_long_at i)

Return the Unsigned Long Value that is the renaminder after dividing the current unsigned long value by the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MOD` (num_at i)

Return the Number Value that is the renaminder after dividing the current number value by the argument.

`Parameters``:`

i- Number

`Returns:` num_at

`*MOD` (time_local_at i)

Return the Unsigned Long Value that is the renaminder after dividing the current unsigned long value by the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MOD` (time_at i)

Return the Unsigned Long Value that is the renaminder after dividing the current unsigned long value by the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MONTH`

Extracts the month from the current system time, and returns that value as an integer from 1 (January) to 12 (December).

`Returns:` num_at

`*MUL` (double_at i)

Return the Double Value after multiplying the argument to the current double value.

`Parameters``:`

i- Double

`Returns:` double_at

`*MUL` (ip_address_at i)

Return the Unsigned Long Value after multiplying the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MUL` (unsigned_long_at i)

Return the Unsigned Long Value after multiplying the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MUL` (num_at i)

Return the Number Value after multiplying the argument to the current number value.

`Parameters``:`

i- Number

`Returns:` num_at

`*MUL` (time_local_at i)

Return the Unsigned Long Value after multiplying the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*MUL` (time_at i)

Return the Unsigned Long Value after multiplying the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*NEG`

Return the Number Value after negating the current number value.

`Returns:` num_at

`*NE` (double_at i)

Returns Boolean TRUE if the double value is not equal to the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`*NE` (ip_address_at i)

Returns Boolean TRUE if the unsigned long value is not equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*NE` (unsigned_long_at i)

Returns Boolean TRUE if the unsigned long value is not equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*NE` (num_at i)

Returns Boolean TRUE if the number value is not equal to the argument.

`Parameters``:`

i- Number

`Returns:` bool_at

`*NE` (text_t s)

Results in Boolean TRUE value if the Text object is not equal to the input argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*NE` (time_at t)

Results in Boolean TRUE value if the time value is not equal to the argument time.

Assume the current time value is GMT 2005 May 1 10h 15m 30s. This is the 1st Sunday of the month of May in 2005.

NE(GMT 2005): FALSE NE(GMT 2005 Dec): TRUE NE(Local 2005 May): TRUE or FALSE depending on the current timezone. NE(GMT 10h): FALSE NE(GMT 10h 30s): FALSE NE(GMT May 10h): FALSE NE(GMT Sun): FALSE NE(GMT May Sun_1): FALSE

`Parameters` (expressions not allowed) `:`

t- Time

`Returns:` bool_at

`*NE` (time_local_at i)

Returns Boolean TRUE if the unsigned long value is not equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*NE` (time_at t)

Results in Boolean TRUE value if the time value is not equal to the argument GMT time value.

`Parameters``:`

t- GMT Time Value

`Returns:` bool_at

`*NORMALIZE_URL`

Normalize URL. Normalizes a URL by doing "percent" decoding. See the description for URLENCODED in the SET_TEXT_MODE function. This performs the equivalent of SET_TEXT_MODE(URLENCODED).DECODE_USING_TEXT_MODE, except that it does not change the value of the current text mode.

`Returns:` text_t

`*PKEY_ENCRYPT_PEM_NO_PADDING` (text_t pem_pkey)

Encrypts the input text using the RSA public key provided by the PEM string and RSA_NO_PADDING padding method. The input text to be encrypted cannot be longer than the public key length minus 11 bytes for padding. For example, for a 1024-bit (128 byte) key, the input text cannot be longer than 128 - 11 = 117 bytes. An Undef error will occur if the input text is too long. A null input will also cause an Undef error. Returns the (unencoded binary) encrypted text, which is typically base-64 encoded for use in a message.

`Parameters``:`

pem_pkey- a text expression that supplies a RSA public key in the PEM format. If the text value is not a valid PEM RSA PUBLIC KEY encoding, an Undef error will occur. Example (a 1024-bit public key):

```
"-----BEGIN RSA PUBLIC KEY-----" +

"MIGJAoGBAKl5vgQEj73Kxp+9yn1v5gPR1pnc4oLM2a0kaWwBOsB6rzCIy6znwnvw" +

"CY1xRvQhRlJSAyJbloL7wZFIJ2FOR8Cz+8ZQWXU2syG+udi4EnWqLgFYowF9zK+o" +

"79az597eNPAjsHZ/C2oL/+6qY5a/f1z8bQPrHC4GpFfAEJhh/+NnAgMBAAE=" +

"-----END RSA PUBLIC KEY-----"
```

`Returns:` text_t

`*PKEY_ENCRYPT_PEM` (text_t pem_pkey)

Encrypts the input text using the RSA public key provided by the PEM string and the RSA_PKCS1_PADDING padding method. The input text to be encrypted cannot be longer than the public key length minus 11 bytes for padding. For example, for a 1024-bit (128 byte) key, the input text cannot be longer than 128 - 11 = 117 bytes. An Undef error will occur if the input text is too

long. A null input will also cause an Undef error. Returns the (unencoded binary) encrypted text, which is typically base-64 encoded for use in a message.

`Parameters``:`

pem_pkey- a text expression that supplies a RSA public key in the PEM format. If the text value is not a valid PEM RSA PUBLIC KEY encoding, an Undef error will occur. Example (a 1024-bit public key):

```
"-----BEGIN RSA PUBLIC KEY-----" +

"MIGJAoGBAKl5vgQEj73Kxp+9yn1v5gPR1pnc4oLM2a0kaWwBOsB6rzCIy6znwnvw" +

"CY1xRvQhRlJSAyJbloL7wZFIJ2FOR8Cz+8ZQWXU2syG+udi4EnWqLgFYowF9zK+o" +

"79az597eNPAjsHZ/C2oL/+6qY5a/f1z8bQPrHC4GpFfAEJhh/+NnAgMBAAE=" +

"-----END RSA PUBLIC KEY-----"
```

`Returns:` text_t

`*PKEY_SIGN_CERTKEY` (text_t certkey_name)

Generates a binary digital signature using the SHA-256 message digest function and an RSA private key from the specified SSL certKey object.

`Parameters``:`

certkey_name- identifies the configured certKey object. Results in an Undef error if the certkey object does not exist or does not contain an RSA private key, or if the signing operation cannot complete.

`Returns:` text_t

`*PKEY_SIGN_XML` (text_t xml_pkey)

Generates a binary digital signature using the SHA-256 message digest function and an RSA private key from the specified XML element.

`Parameters``:`

xml_pkey- an expression that supplies an <RSAKeyValue> element with the private key. Example: <RSAKeyValue> <Modulus>qXm+BASPvcrGn73KfW/ mA9HWmdzigszZrSRpbAE6wHqvMIjLrOfCe/ AJjXFG9CFGUlIDIluWgvvBkUgnYU5HwLP7xlBZdTazIb652LgSdaouAVijAX3Mr6jv1rPn3t408COwdn8Lagv/ 7qpjlr9/XPxtA+scLgakV8AQmGH/42c=</Modulus> <Exponent>AQAB</Exponent>"zNjysxcIJV/ J9cTpIgPp2/x1IXHT5GTH8OMuNad0qtRSLjU1QYUmmkm9QcJJAN+7h8FEXWGabySUzBrHj/ IEbw==" <DP>QavUDQLLQpnPJXtVAo6CYhxOMCd68mwTxYKKNLjmC0pd54SFHllTLPE1FZU5EjK6q3nCeijonpfH+XX DP> <DQ>EiXOKouJzzXTQJC3TqomF7Uf81yQNxWumOqnd11kepXgyfMwyqMvLlAGEkNSEF/ Bz18R3Wv+MIZ/IC3nLBt2xQ==</DQ> <InverseQ>ocuCmz36CP+N2aGqxaU+BKD5+3RLgRq9LFhULEz2jKx0iV9r76jsAxn3sLcTYYO9eqRPy2cz74AU nw==</InverseQ> <D>fTBD773a3GzcmgVdfZlaBLpN1ux2mf5uUVrTUQf7eVFm9egm4/ tzC5A9zjC+I/oscwTH8epL3UfRLdtp05Q6pWfJBXEnGo0QmOFFBK4pLx/ 5JJpPGZ69ovDFEVOUHyiCfKE/g97T4WX3us0nFe1272zwGlHarM1YYwvfeE08UdE=</D> </ RSAKeyValue> Results in an Undef error if the XML element is invalid or does not correctly specify an RSA private key, or if the signing operation cannot complete.

`Returns:` text_t

`*PKEY_VERIFY_CERTKEY` (text_t certkey_name, text_t signature)

Verifies if the input text matches the specified signature generated using the SHA-256 messge digest function and the RSA private key associated with the specified RSA public key in the X.509 certificate in the specified certKey object. Returns true if the signature is verified, false otherwise.

`Parameters``:`

certkey_name- identifies the certkey object containing an X.509 certificate holding the RSA public key.

signature- the binary signature. Results in an Undef error if the certkey object does not exist or does not contain an X.509 certificate with an RSA public key, or if the verification operation cannot complete.

`Returns:` bool_at

`*PKEY_VERIFY_XML` (text_t xml_pkey, text_t signature)

Verifies if the input text matches the specified signature generated using the SHA-256 messge digest function and the RSA private key associated with the RSA public key supplied by the specified XML element. Returns true if the signature is verified, false otherwise.

`Parameters``:`

xml_pkey- an expression that supplies an <RSAKeyVAlue> element with the public key. Example: <RSAKeyValue> <Modulus>qXm+BASPvcrGn73KfW/mA9HWmdzigszZrSRpbAE6wHqvMIjLrOfCe/AJjXFG9CFGUlIDIluWgvvBkUgnYU5HwLP7xlBZdTazIb652LgSdaouAVijAX3Mr6jv1rPn3t408COwdn8Lagv/7qpjlr9/XPxtA+scLgakV8AQmGH/42c=</Modulus> <Exponent>AQAB</Exponent> </RSAKeyValue>

signature- the binary signature. Results in an Undef error if the XML element is invalid or does not correctly specify an RSA public key, or if the verification operation cannot complete.

`Returns:` bool_at

`*PREFIX` (`char` c, `uint` i)

Select a prefix of the Text. The selected prefix is the longest prefix that has at most Count (2nd argument) occurrences of character in the 1st argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

c- Character

i- Count

`Returns:` text_t

`*PREFIX` (`uint` i)

Select a prefix of the Text. The length of the prefix is equal to the number in the argument. If there aren't enough characters in the Text object then the entire Text is selected.

`Parameters``:`

i- Prefix Length

`Returns:` text_t

`*REGEX_MATCH` (`re` regex)

The REGEX_MATCH operator in this object overrides the Text REGEX_MATCH operator to operate on all the instances of the current header type. Returns Boolean TRUE if the input regular

expression matches any instance of the header value. The order in which the header instances will be matched is from the last to the first.

The regular expression has to be of the format: `re<delimiter>regular expression<same delimiter>`

The regular expression cannot be bigger than 1499 characters.

The regular expression should be acceptable by the PCRE regular expression library. Look at http://www.pcre.org/pcre.txt for documentation on the regular expression syntax. In particular, look at the pcrepattern man page.

There are some differences in the allowed syntax w.r.t PCRE syntax. Backreferences are not allowed. It is recommended to not use recursive regular expressions. The dot metacharacter matches newlines also. Unicode is not supported. SET_TEXT_MODE(IGNORECASE) overrides the (?i) internal option specified in the regular expression.

The PCRE library configuration can be seen in the system log, after executing 'nsapimgr -B" call ns_pixl_regex_show_config()"' at the shell prompt.

Some examples:

- HTTP.REQ.HOSTNAME.REGEX_MATCH(re/\[\[:alpha:\]\]+(abc){2,3}/)
- HTTP.REQ.URL.SET_TEXT_MODE(URLENCODED).REGEX_MATCH(re#(a*b+c*)#)
- HTTP.REQ.URL.REGEX_MATCH(re/a(?i)b/) matches ab and aB
- HTTP.REQ.URL.SET_TEXT_MODE(IGNORECASE).REGEX_MATCH(re/ab/) matches ab, aB, Ab and AB
- HTTP.REQ.BODY.REGEX_MATCH(re/(?ixm) (\^ab (.*) cd$) /) does a case-insensitive, multiline match where the dot metacharacter matches newline also. The regex itself can contain whitespace which will be ignored during the matching (x - extended regex).

This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

regex- Regular Expression

`Returns:` bool_at

`*REGEX_REPLACE` (`re` regex, text_t replacement, replacemode_e mode)

Selects the text that matches the given regular expression argument and replaces it with the the text given in the second argument. The third argument specifies whether the first match is only replaced when multiple matches occur in the text or all matches are replaced. The match may occur anywhere within the text - if you wish to "anchor" this, use "\^" at the start of the regex and/or "$" at the end of the regex. When the regular expression does not match the given string then the same string is returned.

For example: HTTP.RES.BODY(999).REGEX_REPLACE(re!\\bpassword:\\s*\\b!, "password: ***", ALL) will replace all occurrences of "password:" with "password: ***" This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

regex- Regular Expression

replacement- String to replace the match

mode- Mode of replacement

`Returns:` text_t

`*REGEX_SELECT` (`re` regex)

The REGEX_SELECT operator in this object overrides the Text REGEX_SELECT operator to operate on all the instances of the current header type. Selects the Text that matches the input regular expression in any instance of the header value. The order in which the header instances will be matched is from the last to the first.

For example: HTTP.REQ.HEADER("via").REGEX_SELECT(re!NS-CACHE-\\d\\.\\d:\\s*\\d{1,3}!) will select "NS-CACHE-7.0: 70" This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

regex- Regular Expression

`Returns:` text_t

`*RELATIVE_BOOT`

Calculates the number of seconds to the closest previous or scheduled reboot, and returns an integer. If the closest boot time is in the past, the integer is negative; if it is in the future, the integer is positive.

`Returns:` num_at

`*RELATIVE_NOW`

Calculates the number of seconds between the current system time and the specified time, and returns an integer showing that number. If the designated time is in the past, the integer is negative; if it is in the future, the integer is positive.

`Returns:` num_at

`*REPEAT` (`uint` i)

Produces a string which contains 'i' sequential copies of the input string.

`Parameters``:`

i- the number of times to repeat the string (0 or more)

`Returns:` text_t

`*RSHIFT` (`uint` i)

Return the Number Value after bitwise right shifting the current number value by the argument number of bits. Note that the number of bits shifted is i modulo 32. For example, let HTTP.REQ.URL.LENGTH be 4. Then, HTTP.REQ.URL.LENGTH.RSHIFT(1) = HTTP.REQ.URL.LENGTH.RSHIFT(33) = 2, since 33 on division by 32 yields a remainder of 1.

`Parameters``:`

i- Right Shift Length

`Returns:` num_at

`*SECONDS`

Extracts the seconds from the current system time, and returns that value as an integer from 0 to 59.

`Returns:` num_at

`*SET_CHAR_SET` (charset_e charset)

Set the character set to use for subsequent functions that use text.

`Parameters` (expressions not allowed) `:`

charset- Character Set

`Returns:` http_date_t

`*SET_TEXT_MODE` (textmode_e mode)

The mode setting of a Text object controls the behavior of many Text operations. The Text mode settings may also control the behavior of some operations in objects (like List) that build upon the Text object. IGNORECASE, NOIGNORECASE - controls whether string comparison is case sensitive or not. URLENCODED - If set then all Text operations are carried out after translating all %HH or %uHHHH encodings in the underlying byte stream. 1. %HH will be translated to the character Y where HH denotes the ascii value of character Y in hexadecimal. For example, the encoded text "http%3a/.html" will be decoded to "http:/.html" 2. %uWWHH will be translated to the character sequence YZ where WW denotes the ascii value of character Y in hexadecimal and HH denotes the ascii value of character Z in hexadecimal. For example, the encoded text "http%u3a2f.html" and "http%u003a/.html" will both be decoded to"http:/.html" NOURLENCODED - Indicates that no percent encodings are present in the Text object. No percent decoding will be performed on the Text object. PLUS_AS_SPACE - If set then all Text operations are carried out after converting occurrences of the plus character to whitespace. For example, the text "hello+world" will be decoded to "hello world" NO_PLUS_AS_SPACE - If set, then the plus character will not be converted to whitespace in the Text object. BACKSLASH_ENCODED - If set, then all Text operations are carried out after performing the following operations: 1. \\XXX will be translated to the character Y where XXX denotes the ascii value of character Y in octal. The valid range of octal values for this type of encoding is \\0 to \\377. For example, the encoded text "http\\72/.html" and "http\\072/.html" will both be decoded to "http:/.html" 2. \\xHH will be translated to the character Y where HH denotes the ascii value of character Y in hexadecimal. For example, the encoded text "http\\x3a/.html" will be decoded to "http:/.html" 3. \\\\uWWXX will be translated to the character sequence YZ where WW denotes the ascii value of character Y in hexadecimal and XX denotes the ascii value of character Z in hexadecimal. For example, the encoded text "http%u3a2f.html" and "http%u003a/.html" will both be decoded to"http:/.html" 4. Occurences of "\\b", "\\n", "\\t", "\\f" and "\\r" are translated to the corresponding ascii characters. NO_BACKSLASH_ENCODED - If set, then backslash decoding will not be performed on the Text object. BAD_ENCODE_RAISE_UNDEF - If set, then UNDEF is raised if either the URLENCODED or BACKSLASH_ENCODED mode is set and a bad encoding corresponding to the specified encoding mode is encountered. NO_BAD_ENCODE_RAISE_UNDEF - If set, then UNDEF will not be raised when a bad encoding is encountered in the Text object. The Text operations operate on characters (as opposed to operating on bytes). By default a single byte represents a character using the ASCII encoding. But if URLENCODED mode is set then 3 bytes may represent a character. A PREFIX(3) operation will select the first 3 characters in the Text object. That means it

may select up to 9 bytes for URLENCODED Text object. In the case of multibyte decodings as a result of %uXXXX or \\\\uXXXX, Text operations which attempt to treat the multiple decoded bytes as distinct characters are not allowed.

`Parameters` (expressions not allowed) `:`

mode- Text Mode

`Returns:` http_date_t

`*SIGNED16_STRING` (endian_e endianness)

Create a signed 16-bit binary string from the number.

`Parameters` (expressions not allowed) `:`

endianness- Select little or big endian

`Returns:` text_t

`*SIGNED32_STRING` (endian_e endianness)

Create a signed 32-bit binary string from the number.

`Parameters` (expressions not allowed) `:`

endianness- Select little or big endian

`Returns:` text_t

`*SIGNED8_STRING`

Create a signed 8-bit binary string from the number.

`Returns:` text_t

`*SKIP` (`char` c, `uint` i)

Select the Text after skipping over a prefix of the current Text. The skipped over prefix is the longest prefix that has at most Count (2nd argument) occurrences of character in the 1st argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

c- Character

i- Count

`Returns:` text_t

`*SKIP` (`uint` i)

Select the Text after skipping over a prefix in the current Text. The length of the prefix is equal to the number in the argument. If there aren't enough characters in the Text object then the entire Text is skipped over.

`Parameters` (expressions not allowed) `:`

i- Prefix Length

`Returns:` text_t

`*STARTSWITH_ANY` (text_t patset_name)

Results in Boolean TRUE value if the Text starts with any of the strings that are bound to the patset or dataset named by the string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` bool_at

`*STARTSWITH_INDEX` (text_t patset_name)

Returns the numerical index of the matching string, if the Text starts with any of the strings that are bound to the patset or dataset named by the string argument. Returns 0 if there is no match. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` num_at

`*STARTSWITH` (text_t start)

Results in Boolean TRUE value if a prefix of the Text object matches the string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

start- String

`Returns:` bool_at

`*STRIP_CHARS` (text_t s)

From the selected text remove the characters specified in the string.

For example: Say the selected text is / "foo.xyz=bar" /. Then on executing STRIP_CHARS('.=') or STRIP_CHARS('..=') the selected text will become /fooxyzbar /. Note that repeating character has same effect as it would be if it present only once. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*STRIP_END_CHARS` (text_t s)

Selects the Text after stripping off characters in the end of the current Text object.

For example: Say the selected text is / "foo.xyz=bar" /. Then on executing STRIP_END_CHARS('ar') the selected text will become /foo.xyz=b /. Note that repeating character has same effect as it would be if it present only once. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*STRIP_END_WS`

Selects the Text after stripping off white space in the end of the current Text object.

`Returns:` text_t

`*STRIP_START_CHARS` (text_t s)

Selects the Text after stripping off characters in the beginning of the current Text object.

For example: Say the selected text is / "foo.xyz=bar" /. Then on executing STRIP_START_CHARS('of') the selected text will become /.xyz=bar /. Note that repeating character has same effect as it would be if it present only once. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*STRIP_START_WS`

Selects the Text after stripping off white space in the beginning of the current Text object.

`Returns:` text_t

`*SUBSTR_ANY` (text_t patset_name)

Select any one sub-string that matches any string in the given patset or dataset. The patset cannot have strings longer than 255 characters. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` text_t

`*SUBSTR` (`uint` start, `uint` len)

Select the Text object of the given length at the given offset. Offset it 0 based. If there aren't enough characters after the offset then all the remaining characters are selected.

`Parameters``:`

start- Offset

len- Length

`Returns:` text_t

`*SUBSTR` (text_t s)

The SUBSTR operator in this object overrides the Text SUBSTR operator to operate on all the instances of the current header type. Selects Text that matches the input string argument. The order in which the instances of the header are matched is from the last instance to the first.

HTTP/1.1 200 OK\\r\\n MyHdr: 111abc\\r\\n Content-Length: 200\\r\\n MyHdr: 111def\\r\\n \\r\\n

For example: HTTP.RES.HEADER("MyHdr").SUBSTR("111") selects "111" in the last instance of MyHdr, the one with value "111def". This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*SUB` (double_at i)

Return the Double Value after subtracting the argument from the current double value.

`Parameters``:`

i- Double

`Returns:` double_at

`*SUB` (ip_address_at i)

Return the Unsigned Long Value after subtracting the argument from the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*SUB` (unsigned_long_at i)

Return the Unsigned Long Value after subtracting the argument from the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*SUB` (num_at i)

Return the Number Value after subtracting the argument from the current number value.

`Parameters``:`

i- Number

`Returns:` num_at

`*SUB` (time_local_at i)

Return the Unsigned Long Value after subtracting the argument from the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*SUB` (time_at i)

Return the Unsigned Long Value after subtracting the argument from the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*SUFFIX` (`char` c, `uint` i)

Select a suffix of the Text. The selected suffix is the longest possible suffix containing at most Count (2nd arg) occurrences of the character in the 1st argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

c- Character

i- Count

`Returns:` text_t

`*SUFFIX` (`uint` i)

Select a suffix of the Text. The length of the suffix is equal to the number in the argument. If there aren't enough characters in the Text object then the entire Text is selected.

`Parameters``:`

i- Suffix Length

`Returns:` text_t

`*TO_LOCAL`

Convert the time to the local time zone

`Returns:` time_local_at

`*TO_LOWER`

Converts the selected text to lower case.

For example, the string "ABCd" is converted to "abcd"

`Returns:` text_t

`*TO_UPPER`

Converts the selected text to upper case.

For example, the string "abcD" is converted to "ABCD"

`Returns:` text_t

`*TRUNCATE` (`char` c, `uint` i)

Select the Text after truncating a suffix from the current Text object. The truncated suffix is the longest possible suffix containing at most Count (2nd arg) occurrences of the character in the 1st argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

c- Character

i- Count

`Returns:` text_t

`*TRUNCATE` (`uint` i)

Select the Text after truncating a suffix of the Text. The length of the suffix truncated is equal to the number in the argument. If there aren't enough characters in the Text then then all the characters are truncated.

`Parameters``:`

i- Suffix Length

`Returns:` text_t

`*TYPECAST_AVP_T`

Convert text_t to avp_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (avp_t : Operations that can be performed on the returned AVPs.

`Note:` An AVP can have multiple instances in a Diameter message. However, the system can access only the first 16 instances.

`Example:`

- To get the first value of AVP code 266 from a request, use: DIAMETER.REQ.AVP(266).VALUE(0).
- To get the fourth value of AVP code 266 from a request, use: DIAMETER.REQ.AVP(266).VALUE(3).
- To check if AVP code 1000 in the response has the vendor-specific bit set, use: DIAMETER.RES.AVP(1000).IS_VENDOR_SPECIFIC.

)

`Returns:` avp_t

`*TYPECAST_AVP_UNUM_T`

Convert text_t to avp_unum_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (avp_unum_t : In Diameter AVP based expressions can be written as DIAMETER.REQ.AVP(<avpcode>). For example Auth-Application-Id AVP (AVP code 258) can be extracted as DIAMETER.REQ.AVP(258) For few of the important AVPs we provide aliases. For example this AVP based expression can also be written as DIAMETER.REQ.AUTH_APPLICATION_ID. This expression returns either a object of class avp_t

or returns a numerical value (object of class unsigned_long_at). The numerical value for this object is derived from the value in first instance of the AVP.)

`Returns:` avp_unum_t

`*TYPECAST_BOOL_AT`

Convert text_t to bool_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (bool_at : Boolean Operations)

`Returns:` bool_at

`*TYPECAST_COOKIE_T`

Convert text_t to cookie_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (cookie_t : The HTTP Cookie type provides operations for a cookie as it appears in the Set-Cookie and Set-Cookie2 header. In this type the Name-Value List operations are also available. The first delimiter is = and the element delimiter is ;. Multiple consecutive ; are treated as one. (Same as applying the method IGNORE_EMPTY_ELEMENTS on a Name-Value List.) You can use the Name-value List operations to access cookie attributes. The name comparison for all list operations is case insensitive. In this type Text operations are also available. Each cookie begins with a COOKIE_NAME=COOKIE_VALUE pair followed by zero or more semi-colon separated attribute-value pairs. If an attribute appears more than once in a cookie, the value associated with the first appearance of the attribute is returned.

Format Cookie: Cookie1=Value;Version=decimal;Value;Domain=Value;Path=Value)

`Returns:` cookie_t

`*TYPECAST_DIAMETER_FLAG_T`

Convert text_t to diameter_flag_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (diameter_flag_t : Provides operation to treat the underlying 1 byte as set of bit flags. then set/unset/test/reset_all operations can be done on flag)

`Returns:` diameter_flag_t

`*TYPECAST_DNS_DOMAINNAME_T`

Convert text_t to dns_domainname_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (dns_domainname_t : This object provides

operations for parsing the DNS domain name as it appears at various places in the DNS data. The format is abc.foo.com.)

`Returns:` dns_domainname_t

`*TYPECAST_DNS_FLAG_T`

Convert text_t to dns_flag_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (dns_flag_t : Provides operations to test/set/unset a flag in dns header.)

`Returns:` dns_flag_t

`*TYPECAST_DOUBLE_AT`

Typecast the Number Value to a Double value.

`Returns:` double_at

`*TYPECAST_DOUBLE_T` (double_format_e format)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error.)

`Parameters` (expressions not allowed) `:`

format- Format

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, double_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one

or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, ip_address_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, num_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, time_local_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, time_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, unsigned_long_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the

beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_HTTP_CACHE_CONTROL_T`

Convert text_t to http_cache_control_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_cache_control_t : This object provides for the ability to work on HTTP Cache-Control headers. The name comparison for all list operations is case insensitive.)

`Returns:` http_cache_control_t

`*TYPECAST_HTTP_CONTENT_LENGTH_T`

Convert text_t to http_content_length_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_content_length_t : The HTTP.REQ.CONTENT_LENGTH or HTTP.RES.CONTENT_LENGTH object can be treated as a HTTP Header or as a Number. The numerical value for this object is derived from the value in the last instance of the Content-Length header.)

`Returns:` http_content_length_t

`*TYPECAST_HTTP_COOKIE_T`

Convert text_t to http_cookie_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_cookie_t : This object provides operations for parsing the HTTP cookie header. The name-value pair is derived from the value in the last instance of Cookie header. The format is Cookie : name0=value0; name1=value1; An HTTP Cookie header can have multiple occurrences. COUNT will return a Number containing how many headers of the current type exist. The name comparison for all list operations is case insensitive. The system does not keep track of more than 15 HTTP headers. The result will be undefined if there are more than 15 instances of the header.)

`Returns:` http_cookie_t

`*TYPECAST_HTTP_DATE_T`

Convert text_t to http_date_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_date_t : The HTTP.REQ.DATE or HTTP.RES.DATE object can be treated as a HTTP header or a Time object. The Time value is derived from the value in the last instance of the Date header. The date formats supported are RFC 822 (updated by RFC 1123), RFC 1036 (obsoletes RFC850) and ANSI C asctime() formats.)

`Returns:` http_date_t

`*TYPECAST_HTTP_HEADER_T` (text_t name)

Convert text_t to http_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_header_t : When typecasting a Text object to HTTP Header a header name must be provided.For example: HTTP.REQ.HEADER("MyHdr").TYPECAST_HTTP_HEADER_T("InHdr"))

`Parameters` (expressions not allowed) `:`

name- Header Name

`Returns:` http_header_t

`*TYPECAST_HTTP_HOSTNAME_T`

Convert text_t to http_hostname_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_hostname_t : This object provides operations for parsing the HTTP hostname as it appears at various places in the HTTP protocol data. The format is abc.foo.com:8080.)

`Returns:` http_hostname_t

`*TYPECAST_HTTP_METHOD_T`

Convert text_t to http_method_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_method_t : This object provides Text operations and HTTP Request Method Enum operations on the HTTP request method.)

`Returns:` http_method_t

`*TYPECAST_HTTP_SET_COOKIE_T`

Convert text_t to http_set_cookie_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_set_cookie_t : HTTP.RES.SET_COOKIE provides operations for parsing and operating on the SET-COOKIE header that is present in the HTTP response. HTTP Set-Cookie header supports Text and HTTP Header operations. For most Text operations the value in the last Set-Cookie header is selected. HTTP Set-Cookie header also supports special operations to extract cookies from the response. It is assumed that there will be only one cookie in a Set-Cookie header.)

`Returns:` http_set_cookie_t

`*TYPECAST_HTTP_URL_T`

Convert text_t to http_url_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_url_t : HTTP.REQ.URL provides operations for parsing and operating on the URL that is present in the first line of the HTTP request header. The supported format is \[<protocol>://<hostname>\]<path>?<query>. The Text object backing a HTTP URL object has the Text Mode set to URLENCODED by default.)

`Returns:` http_url_t

`*TYPECAST_HTTP_VERSION_T`

Convert text_t to http_version_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_version_t : HTTP.REQ.VERSION or HTTP.RES.VERSION provide operations to extract HTTP version information.)

`Returns:` http_version_t

`*TYPECAST_IPV6_ADDRESS_AT`

Convert text_t to ipv6_address_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ipv6_address_at : Provides operations for the 128-bit IPv6 address value. Some general information regarding IPv6 expressions: IPv6 PIXL expressions can be combined with other PIXL expressions using the '+' operator. The output is expected to be the concatenation of the string representations of the individual PIXL expressions. No other operator other than '+' is expected to work when any of the operands is an IPv6 PIXL expression. Also, IPv6 PIXL expressions can be combined with any other type of PIXL expression except a PIXL expression that produces a bool result. In other words, if A and/or B are two IPv6 addresses, A+B should result in the string AB. When one of A or B is an IPv6 address, the other can only be a

number or a string and not a boolean. Further, when A and/or B is an IPv6 address, the only operator allowed between them is '+'.

Example: Let the client source IPv6 address be ABCD:1234::ABCD. Let the server destination IPv4 address be 10.100.10.100. Then the expression CLIENT.IPV6.SRC + SERVER.IP.DST should produce the output "ABCD:1234::ABCD10.100.10.100". Similarly, CLIENT.IPV6.SRC + 5 should produce the result ABCD:1234::ABCD5)

`Returns:` ipv6_address_at

`*TYPECAST_IPV6_ADDRESS_T`

Convert text_t to ipv6_address_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ipv6_address_t : This object represents an IPv6 address present in the 1000:1001:CD10:0000:0000:89AB:4567:CDEF format.)

`Returns:` ipv6_address_t

`*TYPECAST_IPV6_SUBNET_AT`

Convert text_t to ipv6_subnet_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ipv6_subnet_at : Provides operations for the integral IPv6 subnet address value.)

`Returns:` ipv6_subnet_at

`*TYPECAST_IPV6_SUBNET_T`

Convert text_t to ipv6_subnet_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ipv6_subnet_t : This object represents an IPv6 subnet address present in the 1000:1001:CD10:0000:0000:89AB:4567:CDEF/64 format.)

`Returns:` ipv6_subnet_t

`*TYPECAST_IP_ADDRESS_AT`

Typecast the Number Value to an IP Address value.

`Returns:` ip_address_at

`*TYPECAST_IP_ADDRESS_T`

Convert text_t to ip_address_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ip_address_t : Represents an IP address present in the 10.100.200.1 format.)

`Returns:` ip_address_t

`*TYPECAST_IP_OPTIONS_T`

Convert text_t to ip_options_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ip_options_t : IP protocol options)

`Returns:` ip_options_t

`*TYPECAST_IP_OPTIONS_TYPE_T`

Convert text_t to ip_options_type_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ip_options_type_t : IP Options Type)

`Returns:` ip_options_type_t

`*TYPECAST_IP_TOS_T`

Convert text_t to ip_tos_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ip_tos_t : Provides operations to TOS field in IP header.)

`Returns:` ip_tos_t

`*TYPECAST_LIST_T` (`char` sep)

Convert text_t to list_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (list_t : The character separator has to be provided when typecasting a textual context to list type. The current text mode has no effect on the character separator. For example if the current text mode is IGNORECASE and the separator is p then P will not be treated as a separator.)

`Parameters` (expressions not allowed) `:`

sep- Separator

`Returns:` list_t

`*TYPECAST_MAC_ADDRESS_AT`

Convert text_t to mac_address_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (mac_address_at : Provides operations for the 48-bit MAC address value.)

`Returns:` mac_address_at

`*TYPECAST_MAC_ADDRESS_T`

Convert text_t to mac_address_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (mac_address_t : Represents a MAC address present in the 12:34:56:78:9a:bc format.)

`Returns:` mac_address_t

`*TYPECAST_NUM_T` (num_format_e format)

Convert text_t to num_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (num_t : Treat the underlying text as a Number in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error.)

`Parameters` (expressions not allowed) `:`

format- Format

`Returns:` num_t

`*TYPECAST_NUM_T` (num_format_e format, num_at default_value)

Convert text_t to num_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (num_t : Treat the underlying text as a Number in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` num_t

`*TYPECAST_NVLIST_T` (`char` sep1, `char` sep2)

Convert text_t to nvlist_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (nvlist_t : Two character delimiters have to be provided when typecasting a Text object to a Name-Value List. The first delimited separates the name from the value. The second delimiter separates list items. For example typecast_nvlist_t('=', '&') handles a URL query string. The Text Mode has no effect on the character delimiters. For example if the current text mode is IGNORECASE and a delimiter is p then P will not be treated as a delimiter.)

`Parameters` (expressions not allowed) `:`

sep1- delimiter1

sep2- delimiter2

`Returns:` nvlist_t

`*TYPECAST_NVLIST_T` (`char` sep1, `char` sep2, `char` quote)

Convert text_t to nvlist_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (nvlist_t : Two character delimiters and quote-character have to be provided when typecasting a Text object to a Name-Value List that supports quote-character. The first delimited separates the name from the value. The second delimiter separates list items. The third value specifies the quote character. For example typecast_nvlist_t('=', ';', "") handles a name-value list separated by semi-colons that allows quoting. The quote-character specifies that the value can occur within the quotes and the delimiters within the quote-characters should not be taken into account. The Text Mode has no effect on the character delimiters. For example if the current text mode is IGNORECASE and a delimiter is p then P will not be treated as a delimiter.)

`Parameters` (expressions not allowed) `:`

sep1- delimiter1

sep2- delimiter2

quote- quote-character.

`Returns:` nvlist_t

`*TYPECAST_PROTOCOL_BUFFER_T`

Convert text_t to protocol_buffer_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (protocol_buffer_t : gRPC Protocol Buffers interface)

`Returns:` protocol_buffer_t

`*TYPECAST_RADIUS_AVP_T`

Convert text_t to radius_avp_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (radius_avp_t : Operations that can be performed on the returned AVPs.

`Note:` An AVP can have multiple instances in a radius message. However, the system can access only the first 16 instances.

`Example:`

- To get the first value of AVP code 26 from a request, use: radius.REQ.AVP(26).VALUE(0).
- To get the fourth value of AVP code 26 from a request, use: radius.REQ.AVP(26).VALUE(3).

)

`Returns:` radius_avp_t

`*TYPECAST_RADIUS_AVP_VALUE_T`

Convert text_t to radius_avp_value_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (radius_avp_value_t : Provides operations to typecast RADIUS AVP value to Integer value or IP Address.)

`Returns:` radius_avp_value_t

`*TYPECAST_SEQ_TEXT_T`

Convert text_t to seq_text_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (seq_text_t : Represents the Text Sequence class.)

`Returns:` seq_text_t

`*TYPECAST_SERVICEPATH_T`

Convert text_t to servicepath_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (servicepath_t : Operations that can be performed on the service path.

`Example:`

- To get the name of the service path applicable to current subscriber, use: SUBSCRIBER.SERVICEPATH
- To determine If the service function is the next in the service path applicable to scubscriber, use: SUBSCRIBER.SERVICEPATH.IS_NEXT().

)

`Returns:` servicepath_t

`*TYPECAST_SIP_CALLID_HEADER_T`

Convert text_t to sip_callid_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_callid_header_t : This object provides operations for parsing the SIP callid header.)

`Returns:` sip_callid_header_t

`*TYPECAST_SIP_CONTENT_LENGTH_T`

Convert text_t to sip_content_length_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_content_length_t : The SIP.REQ.CONTENT_LENGTH or SIP.RES.CONTENT_LENGTH object can be treated as a SIP Header or as a Number. The numerical value for this object is derived from the value in the last instance of the Content-Length header.)

`Returns:` sip_content_length_t

`*TYPECAST_SIP_FROM_HEADER_T`

Convert text_t to sip_from_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_from_header_t : This object provides operations for parsing the SIP From header.)

`Returns:` sip_from_header_t

`*TYPECAST_SIP_HEADER_T` (text_t name)

Convert text_t to sip_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_header_t : When typecasting a Text object to SIP Header a header name must be provided.For example: SIP.REQ.HEADER("MyHdr").TYPECAST_SIP_HEADER_T("InHdr"))

`Parameters` (expressions not allowed) `:`

name- Header Name

`Returns:` sip_header_t

`*TYPECAST_SIP_HOSTNAME_T`

Convert text_t to sip_hostname_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_hostname_t : This object provides operations for parsing the SIP hostname as it appears at various places in the SIP protocol data. The format is abc.foo.com:5060.)

`Returns:` sip_hostname_t

`*TYPECAST_SIP_METHOD_T`

Convert text_t to sip_method_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_method_t : This object provides Text operations and SIP Request Method Enum operations on the SIP request method.)

`Returns:` sip_method_t

`*TYPECAST_SIP_TO_HEADER_T`

Convert text_t to sip_to_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_to_header_t : This object provides operations for parsing the SIP From header.)

`Returns:` sip_to_header_t

`*TYPECAST_SIP_URL_T`

Convert text_t to sip_url_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_url_t : SIP.REQ.URL provides operations for parsing and operating on the URL that is present in the first line of the SIP request header. The supported format is \[<protocol>://<hostname>\]<path>?<query>. The Text object backing a SIP URL object has the Text Mode set to URLENCODED by default.)

`Returns:` sip_url_t

`*TYPECAST_SIP_VERSION_T`

Convert text_t to sip_version_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_version_t : SIP.REQ.VERSION or SIP.RES.VERSION provide operations to extract SIP version information.)

`Returns:` sip_version_t

`*TYPECAST_SIP_VIA_HEADER_T`

Convert text_t to sip_via_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_via_header_t : This object provides operations for parsing the SIP Via header.)

`Returns:` sip_via_header_t

`*TYPECAST_SSLVPN_MODE_T`

Convert text_t to sslvpn_mode_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sslvpn_mode_t : This object provides Text operations and SSLVPN Mode Enum operations on the SSLVPN request method.)

`Returns:` sslvpn_mode_t

`*TYPECAST_SSL_TEXT_T` (text_t name)

Convert text_t to ssl_text_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ssl_text_t : Treat the underlying text object as SSL Text.)

`Parameters` (expressions not allowed) `:`

name- Name

`Returns:` ssl_text_t

`*TYPECAST_TCP_OPTIONS_T`

Convert text_t to tcp_options_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (tcp_options_t : TCP Protocol Options)

`Returns:` tcp_options_t

`*TYPECAST_TCP_OPTIONS_TYPE_T`

Convert text_t to tcp_options_type_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (tcp_options_type_t : TCP Protocol Options Type)

`Returns:` tcp_options_type_t

`*TYPECAST_TCP_REPEATER_OPTION_T`

Convert text_t to tcp_repeater_option_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (tcp_repeater_option_t : TCP Protocol Option : Repeater)

`Returns:` tcp_repeater_option_t

`*TYPECAST_TEXT_T`

Typecast the Time Value to its string representation.

`Returns:` text_t

`*TYPECAST_TIME_LOCAL_AT`

Typecast the Number Value to a local time value.

`Returns:` time_local_at

`*TYPECAST_TIME_T`

Convert text_t to time_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (time_t : This object treats a Text object as a date string. The formats supported are

1\. RFC822 :: Sun, 06 Nov 1994 08:49:37 GMT 2\. RFC850 :: Sunday, 06-Nov-94 08:49:37 GMT 3\. ASCTIME :: Sun Nov 6 08:49:37 1994 4\. ASCTIME like :: Sun Nov 6 08:49:37 1994 5\. ASCTIME like :: Sun Nov 06 08:49:37 1994 6\. Http Set-Cookie Expiry date :: Sun, 06-Nov-1994 08:49:37 GMT)

`Returns:` time_t

`*TYPECAST_UNSIGNED_LONG_AT`

Typecast the Number Value to a Unsigned Long value.

`Returns:` unsigned_long_at

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error.)

`Parameters` (expressions not allowed) `:`

format- Format

`Returns:` unsigned_long_t

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format, ip_address_at default_value)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` unsigned_long_t

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format, unsigned_long_at default_value)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining

characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` unsigned_long_t

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format, num_at default_value)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` unsigned_long_t

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format, time_local_at default_value)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` unsigned_long_t

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format, time_at default_value)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` unsigned_long_t

`*TYPECAST_UNUM_TEXT_T`

Convert text_t to unum_text_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unum_text_t : Provides operations to treat the underlying OctectString as Binary String or unsigned long value .)

`Returns:` unum_text_t

`*TYPECAST_URL_CATEGORY_T`

Convert text_t to url_category_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (url_category_t : Retrieves URL category and attributes from an URL)

`Returns:` url_category_t

`*TYPECAST_VENDOR_SPEC_APPID_AVP_T`

Convert text_t to vendor_spec_appid_avp_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (vendor_spec_appid_avp_t : Retrieves AVPs that are nested in the grouped AVP Vendor-Specific-Application-Id (code 260). The nested AVPs are:

- Vendor-Id
- Auth-Application-Id
- Acct-Application-Id

For example, to retrieve the Auth-Application-Id AVP from the Vendor-Specific-Application-Id AVP:

- For requests: DIAMETER.REQ.VENDOR_SPECIFIC_APPLICATION_ID.AUTH_APPLICATION_ID
- For responses: DIAMETER.RES.VENDOR_SPECIFIC_APPLICATION_ID.AUTH_APPLICATION_ID

)

`Returns:` vendor_spec_appid_avp_t

`*TYPECAST_VENDOR_SPEC_RADIUS_AVP_T`

Convert text_t to vendor_spec_radius_avp_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (vendor_spec_radius_avp_t :

- Vendor-Id

To retrieve the Vendor-Id from the Vendor-Specific AVP:

- RADIUS.REQ.VENDOR_SPECIFIC.VENDORID

)

`Returns:` vendor_spec_radius_avp_t

`*UNQUOTE` (`char` c)

If selected text is quoted by character c, Remove character c from beginning and end.

For example: Say the selected text is / "foo xyz bar " /. Then on executing UNQUOTE("") the selected text will become /foo xyz bar / This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

c- Character

`Returns:` text_t

`*UNSIGNED16_STRING` (endian_e endianness)

Create an unsigned 16-bit binary string from the number.

`Parameters` (expressions not allowed) `:`

endianness- Select little or big endian

`Returns:` text_t

`*UNSIGNED32_STRING` (endian_e endianness)

Create an unsigned 32-bit binary string from the number.

`Parameters` (expressions not allowed) `:`

endianness- Select little or big endian

`Returns:` text_t

`*UNSIGNED64_STRING` (endian_e endianness)

Create an unsigned 64-bit binary string from the number.

`Parameters` (expressions not allowed) `:`

endianness- Select little or big endian

`Returns:` text_t

`*UNSIGNED8_STRING`

Create an unsigned 8-bit binary string from the number.

`Returns:` text_t

`*URLSET_MATCHES_ANY` (text_t urlset_name)

Results in Boolean TRUE value if and only if the Text matches any of the patterns that are specified in the urlset named by the string argument. The matching is case-insensitive for domains, but case-sensitive for paths. For example:

- HTTP.REQ.HOST.APPEND(HTTP.REQ.URL).URLSET_MATCHES_ANY("urlset_forbidden") returns true when the combined domain and URL matches any pattern in the urlset whose name is "urlset_forbidden".

`Parameters` (expressions not allowed) `:`

urlset_name- urlset name

`Returns:` bool_at

`*URL_CATEGORIZE` (`uint` min_reputation, `uint` max_reputation)

Returns the URL category for the supplied URL with the given minimum and maximum reputation score. Where a score of 5 is most risky and 1 is least risky. If either score is set to 0, that bound would be ignored. By specifying the reputation scores, the function will returned the category with the highest score (most risky) based on the bounds. If there was an error getting the category or if the URL is invalid then it will result in an Undef error. For example: HTTP.REQ.HOST.APPEND(HTTP.REQ.URL).URL_CATEGORIZE(0, 0) returns value when the combined domain and URL is looked up for the URL category with the highest reputation score (most risky).

`Parameters` (expressions not allowed) `:`

min_reputation- Minimum reputation score of URL category

max_reputation- Maximum reputation score of URL category

`Returns:` url_category_t

`*URL_RESERVED_CHARS_SAFE`

Converts URL reserved characters to corresponding '%XX' values and retains the rest. This is a read only operation.

```
Based on RFC3986, following are considered URL unreserved characters:

    Alpha-numeric characters: a-z, A-Z, 0-9

    Hyphen and underscore: "-", "_"

    Dot: "."
```

```
    Tilde: "~"
```

The rest are converted to %XX encoding, 'XX' is the hex-based representation of the input character. If the requirement is to encode all but URL safe characters, please consider using HTTP_URL_SAFE method.

`Returns:` text_t

`*VALUE` (`uint` lineno)

An HTTP header can have multiple occurrences. VALUE(0) will select the value in the last header line of the current type, VALUE(1) will select the value in the last but one header line and so on. The counting goes backward. Only the last 15 instances of a header are accessible. Therefore Instance Number cannot be greater than 14.

HTTP/1.1 200 OK\\r\\n MyHdr: abc\\r\\n Content-Length: 200\\r\\n MyHdr: def\\r\\n \\r\\n

For example: HTTP.RES.HEADER("MyHdr").VALUE(1) will return a Text object referring to "abc\\r\\n".

`Parameters` (expressions not allowed) `:`

lineno- Instance Number

`Returns:` text_t

`*WEEKDAY`

Results in a Number Value between 0 (Sunday) and 6 (Saturday) which gives the week day in the time value.

`Returns:` num_at

`*WEEKDAY_STRING`

Given the numeric day of the week, e.g. SYS.TIME.WEEKDAY, return the long form of the string name for that day, e.g. 0 = "Sunday", 6 = "Saturday".

`Returns:` text_t

`*WEEKDAY_STRING_SHORT`

Given the numeric day of the week, e.g. SYS.TIME.WEEKDAY, return the short form of the string name for that day, e.g. 0 = "Sun", 6 = "Sat".

`Returns:` text_t

`*WITHIN` (time_at time1, time_at time2)

Results in a Boolean TRUE value if the time value lies within all the ranges defined by the Lower and Upper time arguments.

If an element of time like day or hour is left unspecified in the Lower argument then it is assumed to have the lowest value of its range. If an element is left unspecified in the Upper argument then it is assumed to have the highest value of its range. If the year is specified in one of the argument then it must be specified in the other argument as well. The ranges for different elements of time are month 1-12, day 1-31, weekday 0-6, hour 0-23, minutes 0-59 and seconds 0-59. Each element of time defines a range. For the result to be TRUE each element of time in the time value must lie in the corresponding range present in the Lower and Upper arguments.

Assume the time value is GMT 2005 May 10 10h 15m 30s. This is the second Tuesday of the month. WITHIN(GMT 2004, GMT 2006): TRUE WITHIN(GMT 2004 Jan, GMT 2006 Mar): FALSE (May doesn't fall in the Jan-Mar range.) WITHIN(GMT Feb, GMT): TRUE (May falls in the Feb-Dec range.) WITHIN(GMT Sun_1, GMT Sun_3): TRUE (2nd Tuesday lies within 1st Sunday and the 3rd Sunday.) WITHIN(GMT 2005 May 1 10h, GMT May 2005 1 17h): TRUE WITHIN(LOCAL 2005 May 1, LOCAL May 2005 1): Answer depends on the NetScaler system's timezone.

`Parameters` (expressions not allowed) `:`

time1- Lower Time

time2- Upper Time

`Returns:` bool_at

`*XML_DECRYPT` (text_t certKeyName)

Decrypt the selected content, which was encrypted using the W3C XML Encryption standard.

`Parameters` (expressions not allowed) `:`

certKeyName- identifies the certkey object containing the RSA private key to be used to decrypt the bulk encryption key in the selected EncryptedData element.

`Returns:` text_t

`*XML_ENCRYPT` (text_t certKeyName, encrypt_method_e method)

Encrypt the selected cleartext using the W3C XML Encryption standard.

`Parameters` (expressions not allowed) `:`

certKeyName- identifies the certkey object containing an X.509 certificate with the RSA public key to be used to encrypt the generated bulk encryption key. Note that the certKey object need not, and usually will not, include the associated RSA private key.

method- specifies the bulk encryption method (rc4, des3, aes128, aes192, or aes256) used to encrypt the content.

`Returns:` text_t

`*XML_ENCRYPT` (text_t certKeyName, encrypt_method_e method, `uint` flags)

Encrypt the selected cleartext using the W3C XML Encryption standard.

`Parameters` (expressions not allowed) `:`

certKeyName- identifies the certkey object containing an X.509 certificate with the RSA public key to be used to encrypt the generated bulk encryption key. Note that the certKey object need not, and usually will not, include the associated RSA private key.

method- specifies the bulk encryption method (rc4, des3, aes128, aes192, or aes256) used to encrypt the content.

flags- optional bit mask to specify optional elements in the EncryptedData element. These are hints to tell the receiver what private key to use to decrypt the bulk encryption key, providing information from the certKey's X.509 certificate.

- 1 - include a KeyName element with the certKeyName;
- 2 - include a KeyValue element with the RSA public key from the certificate;
- 4 - include an X509IssuerSerial element with the certificate serial number and issuer DN;
- 8 - include an X509SubjectName element with the certificate subject DN;
- 16 - include an X509Certificate element with the entire certificate;

`Returns:` text_t

`*XPATH_HTML_WITH_MARKUP` (`xpath_str` xpathex)

Applies an XPath expression to the DOM for an HTML document and returns the selected node-set or string, including markup like element tags. node-sets are converted to strings using the standard XPath string conversion routine. The selected portion of the document can be used as the target for rewrite actions.

Examples: HTTP.REQ.BODY(1000).XPATH_HTML_WITH_MARKUP(xp%//md/head/title%) returns the <title> element in the document's <head> This can be used in a rewrite action to replace or delete the <title> element.

`Parameters` (expressions not allowed) `:`

xpathex- XPath Expression

`Returns:` text_t

`*XPATH_HTML` (`xpath_bool` xpathex)

Applies an XPath expression to the DOM for an HTML document and a boolean value.

Examples: HTTP.RES.BODY(1000).XPATH_HTML(xp%boolean(/md/head/meta)%) returns true if the <meta> element exists as a child of <head> element.

`Parameters` (expressions not allowed) `:`

xpathex- XPath Expression

`Returns:` bool_at

`*XPATH_HTML` (`xpath_double` xpathex)

Applies an XPath expression to the DOM for an HTML document and a double value.

Examples: HTTP.RES.BODY(1000).XPATH_HTML(xp%number(//video/@height)%) returns the numeric value of the height attribute of the first <video> element.

`Parameters` (expressions not allowed) `:`

xpathex- XPath Expression

`Returns:` double_at

`*XPATH_HTML` (`xpath_str` xpathex)

Applies an XPath expression to the DOM for an HTML document and returns the selected node-set or string. node-sets are converted to strings using the standard XPath string conversion routine.

Examples: HTTP.REQ.BODY(1000).XPATH_HTML(xp%//img/@src%) returns the string value of the src attribute of the first

HTTP_HEADER_T

The HTTP.REQ.HEADER("header name") or HTTP.RES.HEADER("header name") object represents the multiple lines of a particular HTTP header type. This object is also a Text object. Direct Text operations on this object will mostly operate only on the value in the last header line of this type. Some Text operations like CONTAINS have been overridden to operate on values in all the header lines of this type.

This topic lists the expressions that are provided by this class.

`*Note` *: Expressions with the * symbol are inherited / promoted from text_t

`AFTER_REGEX` (`re` regex)

The AFTER_REGEX operator in this object overrides the Text AFTER_REGEX operator to operate on all the instances of the current header type. Selects the Text after the text that matches the input regular expression in any instance of the header value. The order in which the header instances will be matched is from the last to the first.

For example: HTTP.REQ.HEADER("etag").AFTER_REGEX(re/KX/) will select "DAPPER" from "KXDAPPER". This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

regex- Regular Expression

`Returns:` text_t

`*AFTER_STR` (text_t s)

The AFTER_STR operator in this object overrides the Text AFTER_STR operator to operate on all the instances of the current header type. Selects Text after the first occurrence of the input string argument. The order in which the instances of the header are matched is from the last instance to the first.

HTTP/1.1 200 OK\\r\\n MyHdr: 111abc\\r\\n Content-Length: 200\\r\\n MyHdr: 111def\\r\\n \\r\\n

Examples: HTTP.RES.HEADER("MyHdr").AFTER_STR("111") selects "def" in the last instance of MyHdr, the one with value "111def". HTTP.RES.HEADER("MyHdr").AFTER_STR("1ab") selects "c" in the first instance of MyHdr, the one with value "abc111". This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*BEFORE_REGEX` (`re` regex)

The BEFORE_REGEX operator in this object overrides the Text BEFORE_REGEX operator to operate on all the instances of the current header type. Selects the Text before the text that matches the input regular expression in any instance of the header value. The order in which the header instances will be matched is from the last to the first.

For example: HTTP.RES.HEADER("content-type").BEFORE_REGEX(re#/#) will select "text" from "text/plain". This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed)`:`

regex- Regular Expression

`Returns:` text_t

`*BEFORE_STR` (text_t s)

The BEFORE_STR operator in this object overrides the Text BEFORE_STR operator to operate on all the instances of the current header type. Selects Text before the first occurrence of the input string argument. The order in which the instances of the header are matched is from the last instance to the first.

HTTP/1.1 200 OK\\r\\n MyHdr: abc111\\r\\n Content-Length: 200\\r\\n MyHdr: def111\\r\\n \\r\\n

Examples: HTTP.RES.HEADER("MyHdr").BEFORE_STR("111") selects "def" in the last instance of MyHdr, the one with value "def111". HTTP.RES.HEADER("MyHdr").BEFORE_STR("bc1") selects "a" in the first instance of MyHdr, the one with value "abc111". This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*CONTAINS_ANY` (text_t patclass_name)

The CONTAINS_ANY in this object overrides the Text CONTAINS_ANY operator to operate on all the instances of the current header type. Returns Boolean TRUE if any of the patterns associated with input patclass is present in any instance of the header value. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patclass_name- Patclass Name

`Returns:` bool_at

`*CONTAINS_INDEX` (text_t patclass_name)

The CONTAINS_INDEX in this object overrides the Text CONTAINS_INDEX operator to operate on all the instances of the current header type. Returns the index of the matching pattern associated with input patclass that is present in any instance of the header value. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patclass_name- Patclass Name

`Returns:` num_at

`*CONTAINS` (text_t s)

The CONTAINS in this object overrides the Text CONTAINS operator to operate on all the instances of the current header type. Returns Boolean TRUE if the input Pattern String is present in any instance of the header value.

GET / HTTP/1.1\\r\\n Host: abc.com\\r\\n MyHdr: abc\\r\\n Content-Length: 200\\r\\n MyHdr: def\\r\\n

HTTP/1.1 200 OK\\r\\n MyHdr: abc\\r\\n Content-Length: 200\\r\\n MyHdr: def\\r\\n \\r\\n

Examples: HTTP.RES.HEADER("MyHdr").CONTAINS("de") is TRUE.
HTTP.RES.HEADER("MyHdr").CONTAINS("bcd") is FALSE.
HTTP.REQ.HEADER("MyHdr").CONTAINS("de") is TRUE.
HTTP.REQ.HEADER("MyHdr").CONTAINS("bcd") is FALSE. The system does not concatenate the different values. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- Pattern String

`Returns:` bool_at

`*COUNT`

An HTTP header can have multiple occurrences. COUNT will return a Number containing how many headers of the current type exist.

HTTP/1.1 200 OK\\r\\n MyHdr: abc\\r\\n Content-Length: 200\\r\\n MyHdr: def\\r\\n \\r\\n

For example: HTTP.RES.HEADER("MyHdr").COUNT will return Number 2. The system does not keep track of more than 15 HTTP headers. The result will be undefined if there are more than 15 instances of the header.

`Returns:` num_at

`*EQUALS_ANY` (text_t patset_name)

The EQUALS_ANY in this object overrides the Text EQUALS_ANY operator to operate on all the instances of the current header type. Returns Boolean TRUE if any of the patterns associated with input patset is equal to any instance of the header value. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed)`:`

patset_name- Patset Name

`Returns:` bool_at

`*EQUALS_INDEX` (text_t patset_name)

The EQUALS_INDEX in this object overrides the Text EQUALS_INDEX operator to operate on all the instances of the current header type. Returns the index of the matching pattern associated with input patset is equal to any instance of the header value. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed)`:`

patset_name- Patset Name

`Returns:` num_at

`*EXISTS`

Returns TRUE if an instance of the current header type exists.

`Returns:` bool_at

`*INSTANCE` (`uint` lineno)

An HTTP header can have multiple occurrences. INSTANCE(0) will select the last header line of the current type, INSTANCE(1) will select the last but one header line and so on. The counting goes backward. Only the last 15 instances of a header are accessible. Therefore Instance Number cannot be greater than 14.

HTTP/1.1 200 OK\\r\\n MyHdr: abc\\r\\n Content-Length: 200\\r\\n MyHdr: def\\r\\n \\r\\n

For example: HTTP.RES.HEADER("MyHdr").INSTANCE(1) will return a Text object referring to "MyHdr: abc\\r\\n". It can not be used in HTTP response processing contexts.

`Parameters` (expressions not allowed) `:`

lineno- Instance Number

`Returns:` text_t

`*REGEX_MATCH` (`re` regex)

The REGEX_MATCH operator in this object overrides the Text REGEX_MATCH operator to operate on all the instances of the current header type. Returns Boolean TRUE if the input regular expression matches any instance of the header value. The order in which the header instances will be matched is from the last to the first.

The regular expression has to be of the format: `re<delimiter>regular expression<same delimiter>`

The regular expression cannot be bigger than 1499 characters.

The regular expression should be acceptable by the PCRE regular expression library. Look at http://www.pcre.org/pcre.txt for documentation on the regular expression syntax. In particular, look at the pcrepattern man page.

There are some differences in the allowed syntax w.r.t PCRE syntax. Backreferences are not allowed. It is recommended to not use recursive regular expressions. The dot metacharacter

matches newlines also. Unicode is not supported. SET_TEXT_MODE(IGNORECASE) overrides the (?i) internal option specified in the regular expression.

The PCRE library configuration can be seen in the system log, after executing 'nsapimgr -B" call ns_pixl_regex_show_config()"' at the shell prompt.

Some examples:

- HTTP.REQ.HOSTNAME.REGEX_MATCH(re/\[\[:alpha:\]\]+(abc){2,3}/)
- HTTP.REQ.URL.SET_TEXT_MODE(URLENCODED).REGEX_MATCH(re#(a*b+c*)#)
- HTTP.REQ.URL.REGEX_MATCH(re/a(?i)b/) matches ab and aB
- HTTP.REQ.URL.SET_TEXT_MODE(IGNORECASE).REGEX_MATCH(re/ab/) matches ab, aB, Ab and AB
- HTTP.REQ.BODY.REGEX_MATCH(re/(?ixm) (\^ab (.*) cd$) /) does a case-insensitive, multiline match where the dot metacharacter matches newline also. The regex itself can contain whitespace which will be ignored during the matching (x - extended regex).

This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

regex- Regular Expression

`Returns:` bool_at

`*REGEX_SELECT` (`re` regex)

The REGEX_SELECT operator in this object overrides the Text REGEX_SELECT operator to operate on all the instances of the current header type. Selects the Text that matches the input regular expression in any instance of the header value. The order in which the header instances will be matched is from the last to the first.

For example: HTTP.REQ.HEADER("via").REGEX_SELECT(re!NS-CACHE-\\d\\.\\d:\\s*\\d{1,3}!) will select "NS-CACHE-7.0: 70" This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

regex- Regular Expression

`Returns:` text_t

`*SUBSTR` (text_t s)

The SUBSTR operator in this object overrides the Text SUBSTR operator to operate on all the instances of the current header type. Selects Text that matches the input string argument. The order in which the instances of the header are matched is from the last instance to the first.

HTTP/1.1 200 OK\\r\\n MyHdr: 111abc\\r\\n Content-Length: 200\\r\\n MyHdr: 111def\\r\\n \\r\\n

For example: HTTP.RES.HEADER("MyHdr").SUBSTR("111") selects "111" in the last instance of MyHdr, the one with value "111def". This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*TYPECAST_TEXT_T`

Convert http_header_t to text_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (text_t : Designates any piece of text.)

`Returns:` text_t

`*VALUE` (`uint` lineno)

An HTTP header can have multiple occurrences. VALUE(0) will select the value in the last header line of the current type, VALUE(1) will select the value in the last but one header line and so on. The counting goes backward. Only the last 15 instances of a header are accessible. Therefore Instance Number cannot be greater than 14.

HTTP/1.1 200 OK\\r\\n MyHdr: abc\\r\\n Content-Length: 200\\r\\n MyHdr: def\\r\\n \\r\\n

For example: HTTP.RES.HEADER("MyHdr").VALUE(1) will return a Text object referring to "abc\\r\\n".

`Parameters` (expressions not allowed) `:`

lineno- Instance Number

`Returns:` text_t

`*AFTER_STR_ANY` (text_t patset_name)

Selects the Text that is present after the first occurrence of any of the strings that are bound to the patset named by the string argument. If there is no match to any of the strings bound to the patset in the current Text object then the result Text object has 0 length. The patset cannot have strings longer than 255 characters. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` text_t

`*APPEND` (bool_at b)

Appends the given boolean's string representation to the current string.

`Parameters``:`

b- the boolean value to append.

`Returns:` text_t

`*APPEND` (double_at i)

Appends the given double's string representation to the current string.

`Parameters``:`

i- the double value to append.

`Returns:` text_t

`*APPEND` (ip_address_at addr)

Appends the given IPv4's string representation to the current string.

`Parameters``:`

addr- the IPv4 address to append.

`Returns:` text_t

`*APPEND` (num_at i)

Appends the given number's string representation to the current string.

`Parameters``:`

i- the number value to append.

`Returns:` text_t

`*APPEND` (time_local_at t)

Appends the given time's string representation to the current string.

`Parameters``:`

t- the time value to append.

`Returns:` text_t

`*APPEND` (time_at t)

Appends the given time's string representation to the current string.

`Parameters``:`

t- the time value to append.

`Returns:` text_t

`*APPEND` (unsigned_long_at i)

Appends the given unsigned long's string representation to the current string.

`Parameters``:`

i- the unsigned long value to append.

`Returns:` text_t

`*APPEND` (ipv6_address_at addr)

Appends the given IPv6's string representation to the current string.

`Parameters``:`

addr- the IPv6 address to append.

`Returns:` text_t

`*APPEND` (ipv6_subnet_at addr)

Appends the given IPv6 subnet's string representation to the current string.

`Parameters``:`

addr- the IPv6 subnet to append.

`Returns:` text_t

`*APPEND` (mac_address_at addr)

Appends the given MAC's string representation to the current string.

`Parameters``:`

addr- the MAC address to append.

`Returns:` text_t

`*APPEND` (text_t str)

Appends the given string to the current string.

`Parameters``:`

str- the string to append.

`Returns:` text_t

`*APPEND` (time_at t)

Appends the given time's string representation to the current string.

`Parameters``:`

t- the time value to append.

`Returns:` text_t

`*B64DECODE`

Decodes the selected text using base64 decoding.

For example, the string "TWFu" is converted to "Man"

`Returns:` text_t

`*B64ENCODE`

Encodes the selected text using base64 encoding.

For example, the string "Man" is converted to "TWFu"

`Returns:` text_t

`*BEFORE_STR_ANY` (text_t patset_name)

Selects the Text that is present before the first occurrence of any of the strings that are bound to the patset or datasetnamed by the string argument. If there is no match to any of the strings bound to the patset in the current Text object then the result Text object has 0 length. The patset cannot have strings longer than 255 characters. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` text_t

`*BETWEEN` (text_t start, text_t end)

Results in Boolean TRUE value if length of the Text object is greater than or equal to the sum of the Start and End argument lengths and if the prefix of the Text object matches the Start string argument and if the Suffix of the Text object matches the End string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

start- Start

end- End

`Returns:` bool_at

`*BIN_DECODE` (binary_encoding_e encoding)

Decode the encoded input into its original byte sequence. An incorrectly enooded input will result in an Undef error.

`Parameters` (expressions not allowed) `:`

encoding- specifies how the bytes are encoded.

`Returns:` text_t

`*BIN_ENCODE` (binary_encoding_e encoding)

Encode the input byte sequence. Note that BIN_ENCODE(hex_colons) is equivalent to BLOB_TO_HEX().

`Parameters` (expressions not allowed) `:`

encoding- specifies how the bytes are to be encoded.

`Returns:` text_t

`*BLOB_TO_HEX`

Convert to hexadecimal representation and select text.

For example, the byte string abc is converted to 61:62:63.

`Returns:` text_t

`*COMPARE` (text_t s)

Results in a Number Value which is the result of comparison of the input argument with the Text object. The result is greater than 0 if the Text object is lexicographically greater than the argument. The result is 0 if the Text object and the argument match. The result is less than 0 if the Text object is lexicographically lesser than the argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` num_at

`*CRC32`

Returns a 32-bit integer computed by applying a CRC (cyclic redundancy check) function to the selected text. This is the CRC function used by Ethernet, MPEG-2, PKZIP, GZIP, PNG, and many other applications. For example, the expression to compute the CRC value of the (first 1000 bytes of the) body of an HTTP request is: HTTP.REQ.BODY(1000).CRC32

`Returns:` num_at

`*DECODE_USING_TEXT_MODE`

Decodes the selected text using the currently configured text encoding methods like URLENCODED, BACKSLASH_ENCODED, PLUS_AS_SPACE, NOURLENCODED, NO_BACKSLASH_ENCODED and NO_PLUS_AS_SPACE. Text encoding methods are set using SET_TEXT_MODE method.

`Returns:` text_t

`*DECRYPT`

Decrypt the selected base64-encoded ciphertext using the configured encryptionParams.

`Returns:` text_t

`*DECRYPT` (binary_encoding_e in_encoding)

Decrypt the selected ciphertext using the configured encryptionParams.

`Parameters` (expressions not allowed) `:`

in_encoding- specifies how the input ciphertext is encoded. If the ciphertext is not encoded as specified, causes an Undef error.

`Returns:` text_t

`*DECRYPT` (text_t encryptionKey)

Decrypt the selected base64-encoded encrypted bytes using the configured encryption key.

`Parameters` (expressions not allowed) `:`

encryptionKey- identifies the encryptionKey object to provide the cipher method, mode, padding, key, encrypted format and optional initialization vector (IV).

`Returns:` text_t

`*DECRYPT` (text_t encryptionKey, binary_encoding_e in_encoding)

Decrypt the selected base64-encoded encrypted bytes using the configured encryption key.

`Parameters` (expressions not allowed) `:`

encryptionKey- identifies the encryptionKey object to provide the cipher method, mode, padding, key, encrypted format, and optional initialization vector (IV).

in_encoding- specifies how the input ciphertext is encoded. If the ciphertext is not encoded as specified, causes an Undef error.

`Returns:` text_t

`*DIGEST` (digest_method_e method)

Returns a byte sequence computed by applying the the specified message digest method to the selected text.

`Parameters` (expressions not allowed) `:`

method- digest method to apply to the input text

`Returns:` text_t

`*ENCRYPT`

Encrypt the selected plaintext bytes using the configured encryptionParams. The resulting ciphertext is base64-encoded.

`Returns:` text_t

`*ENCRYPT` (binary_encoding_e out_encoding)

Encrypt the selected plaintext bytes using the configured encryptionParams.

`Parameters` (expressions not allowed) `:`

out_encoding- specifies how the resulting ciphertext is encoded.

`Returns:` text_t

`*ENCRYPT` (text_t encryptionKey)

Encrypt the selected cleartext bytes using the configured encryption key.

`Parameters` (expressions not allowed) `:`

encryptionKey- identifies the encryptionKey object to provide the cipher method, mode, padding, key, encrypted format and optional initialization vector (IV).

`Returns:` text_t

`*ENCRYPT` (text_t encryptionKey, binary_encoding_e out_encoding)

Encrypt the selected cleartext bytes using the configured encryption key.

`Parameters` (expressions not allowed) `:`

encryptionKey- identifies the encryptionKey object to provide the cipher method, mode, padding, key, encrypted format and optional initialization vector (IV).

out_encoding- specifies how the resulting ciphertext is encoded.

`Returns:` text_t

`*ENDSWITH_ANY` (text_t patset_name)

Results in Boolean TRUE value if the Text ends with any of the strings that are bound to the patset or dataset named by the string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` bool_at

`*ENDSWITH_INDEX` (text_t patset_name)

Returns the numerical index of the matching string, if the Text ends with any of the strings that are bound to the patset or dataset named by the string argument. Returns 0 if there is no match. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` num_at

`*ENDSWITH` (text_t end)

Results in Boolean TRUE value if a suffix of the Text object matches the string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

end- String

`Returns:` bool_at

`*EQ` (text_t s)

Results in Boolean TRUE value if the Text object matches the input argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*GET_SIGNED16` (`uint` n, endian_e endianness)

Get the 16-bit signed binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

endianness- Select little or big endian

`Returns:` num_at

`*GET_SIGNED32` (`uint` n, endian_e endianness)

Get the 32-bit signed binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

endianness- Select little or big endian

`Returns:` num_at

`*GET_SIGNED8` (`uint` n)

Get the 8-bit signed binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

`Returns:` num_at

`*GET_UNSIGNED16` (`uint` n, endian_e endianness)

Get the 16-bit unsigned binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

endianness- Select little or big endian

`Returns:` num_at

`*GET_UNSIGNED32` (`uint` n, endian_e endianness)

Get the 32-bit unsigned binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

endianness- Select little or big endian

`Returns:` unsigned_long_at

`*GET_UNSIGNED64` (`uint` n, endian_e endianness)

Get the 64-bit unsigned binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

endianness- Select little or big endian

`Returns:` unsigned_long_at

`*GET_UNSIGNED8` (`uint` n)

Get the 8-bit unsigned binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

`Returns:` num_at

`*GET_URLSET_METADATA` (text_t urlset_name)

Returns metadata value corresponding to pattern in the urlset. The matching is case-insensitive for domains, but case-sensitive for paths. If no pattern is matched within the urlset, the return value is a NULL string. For example:

- HTTP.REQ.HOST.APPEND(HTTP.REQ.URL).GET_URLSET_METADATA("urlset_forbidden") returns value when the combined domain and URL is looked up in the urlset whose name is "urlset_forbidden".

`Parameters` (expressions not allowed) `:`

urlset_name- urlset name

`Returns:` text_t

`*GE` (text_t s)

Results in Boolean TRUE value if the Text object is greater than or equal to the input argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*GRPC`

Interprets a text_t string as a Protocol Buffer (protocol_buffer_t type). Example: HTTP.REQ.BODY(1000).GRPC.STRING(1).EQ("bookname")

`Returns:` protocol_buffer_t

`*GT` (text_t s)

Results in Boolean TRUE value if the Text object is greater than the input argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*HASH`

Returns a positive 31 bit integer value computed by applying a proprietary NetScaler hash function to the selected text. This function is not case- sensitive and ignores whitespaces. For example, applying the HASH function to two strings "Ab c" and "abc" would produce the same value. This function should not be used for security purposes; use instead the DIGEST function with one of the standard digest methods.

`Returns:` num_at

`*HMAC` (text_t hmacKey)

Returns a byte sequence computed by applying the HMAC (Hash Message Authenticastion Code) function to the selected text using the configured HMAC key.

`Parameters` (expressions not allowed) `:`

hmacKey- indentifies the hmacKey object to provide the digest (hash) method and the key.

`Returns:` text_t

`*HMAC` (text_t hmacKey, binary_encoding_e out_encoding)

Returns a byte sequence computed by applying the HMAC (Hash Message Authenticastion Code) function to the selected text using the configured HMAC key .

`Parameters` (expressions not allowed) `:`

hmacKey- indentifies the hmacKey object to provide the digest (hash) method and the key.

out_encoding- specifies how the resulting HMAC is encoded.

`Returns:` text_t

`*HTML_XML_SAFE`

Apply XML safe transform and select text.

Converts '<', '>' and '&' in the input text to '<', '>' and '&' respectively; other characters in the input are not modified. This transform safeguards against XSS based attacks. This is a read only operation.

`Returns:` text_t

`*HTTP_HEADER_SAFE`

Apply Header safe transform and select text. Converts all new line ('\\n') characters present in the input text to '%0A' so that they can safely be used in HTTP headers. This transform safeguards against response-splitting attacks. This is a read only operation.

`Returns:` text_t

`*HTTP_URL_SAFE`

Apply URL safe transform and select text. Converts URL unsafe characters to corresponding '%xx' values and retains the rest. This is a read only operation.

```
Based on RFC2396, following are considered URL safe characters:

    Alpha-numeric characters: a-z, A-Z, 0-9

    Hyphen and underscore: "-", "_"

    Dot: "."

    Exclamation mark: "!"

    Tilde: "~"

    Asterix: "&ast;"

    Single quote: "'"

    Open and close parentheses: "(", ")"

    Semi-colon: ";"

    Colon: ":"

    At symbol: "@"

    Question mark: "?"

    Equals: "="

    Dollar: "$"

    Percent: "%"
```

```
    Ampersand: "&"

    Plus: "+"

    Comma: ","

    Forward slash: ".html"
```

The rest are converted to %XX encoding, 'XX' is the hex-based representation of the input character. If the requirement is to encode all but URL unreserved characters, please consider using URL_RESERVED_CHARS_SAFE method.

`Returns:` text_t

`*IS_BOOL_AT`

Results in Boolean TRUE value if the Text is of boolean type.

`Returns:` bool_at

`*IS_DOUBLE_AT`

Results in Boolean TRUE value if the Text is of double data type.

`Returns:` bool_at

`*IS_IPV6_AT`

Results in Boolean TRUE value if the Text is of IPv6 data type.

`Returns:` bool_at

`*IS_IPV6_SUBNET_AT`

Results in Boolean TRUE value if the Text is of IPv6 subnet data type.

`Returns:` bool_at

`*IS_IP_AT`

Results in Boolean TRUE value if the Text is of IPv4 data type.

`Returns:` bool_at

`*IS_MAC_ADDRESS_AT`

Results in Boolean TRUE value if the Text is of mac address data type.

`Returns:` bool_at

`*IS_NUM_AT`

Results in Boolean TRUE value if the Text is of number type.

`Returns:` bool_at

`*IS_NUM_AT` (num_format_e format)

Results in Boolean TRUE value if the Text is of number type with given input base.

`Parameters` (expressions not allowed) `:`

format- number format

`Returns:` bool_at

`*IS_STRINGMAP_KEY` (text_t string_map_name)

Returns true if the string that it operates on is present in the string map. Text mode IGNORECASE, NOIGNORECASE - controls whether key lookup in string map is case sensitive or not. For example:

- HTTP.REQ.URL.IS_STRINGMAP_KEY("url_stringmap") returns true if value of HTTP.REQ.URL is present as key in the string map whose name is "url_stringmap".
- HTTP.REQ.URL.SET_TEXT_MODE(IGNORECASE). IS_STRINGMAP_KEY("url_stringmap") returns true if value of HTTP.REQ.URL is present as key in the string map whose name is "url_stringmap". Key lookup in this case is done case-insensitively.

`Parameters` (expressions not allowed) `:`

string_map_name- identifies the string map.

`Returns:` bool_at

`*IS_TIME_AT`

Results in Boolean TRUE if the Text follows any of the standard time formats given below, otherwise false. Tue, 05 Nov 1994 08:12:31 GMT RFC822 Tuesday, 05-Nov-94 08:12:31 GMT RFC850 Tue Nov 4 08:12:31 1994 asctime

`Returns:` bool_at

`*IS_UNSIGNED_LONG_AT`

Results in Boolean TRUE value if the Text is of unsigned long data type.

`Returns:` bool_at

`*IS_UNSIGNED_LONG_AT` (num_format_e format)

Results in Boolean TRUE value if the Text is of unsigned long data type with given input base.

`Parameters` (expressions not allowed) `:`

format- number format

`Returns:` bool_at

`*JWT_VERIFY_CERTKEY` (text_t certkey_name)

Verifies the signature on the input JSON Web Token (JWT), using the RSA public key in the X.509 certificate in the specified certkey object. The token has the format HEADER.PAYLOAD.SIGNATURE where

- HEADER is a base64-encoded JSON structure indicating a signature algorithm and token type, e.g.'{"alg":"RS256","typ":"JWT"}'
- PAYLOAD is a base64-encoded JSON structure with asserted claims, e.g. '{"loggedInAs":"admin","iat":1422779638}'
- SIGNATURE is the base64-encoded bytes for the signature on HEADER.PAYLOAD.

Returns true if the signature is verified for the header and payload using the specified public key; false if the signature is not verified

`Parameters``:`

certkey_name- identifies the certkey object containing an X.509 certificate holding the RSA public key. Results in an Undef error if the certkey object does not exist or does not contain an X.509 certificate with an RSA public key, if the token is not correctly formatted, or if the verification operation cannot complete.

`Returns:` bool_at

`*JWT_VERIFY_XML` (text_t xml_pkey)

Verifies the signature on the input JSON Web Token (JWT), using the RSA public key supplied by the specified XML element. The token has the format HEADER.PAYLOAD.SIGNATURE where

- HEADER is a base64-encoded JSON structure indicating a signature algorithm and token type, e.g.'{"alg":"RS256","typ":"JWT"}'
- PAYLOAD is a base64-encoded JSON structure with asserted claims, e.g. '{"loggedInAs":"admin","iat":1422779638}'
- SIGNATURE is the base64-encoded bytes for the signature on HEADER.PAYLOAD.

Returns true if the signature is verified for the header and payload using the specified public key; false if the signature is not verified

`Parameters``:`

xml_pkey- an expression that supplies an <RSAKeyValue> element with the public key. Results in an Undef error if the XML element is invalid or does not correctly specify an RSA public key, if the token is not correctly formatted, or if the verification operation cannot complete.

`Returns:` bool_at

`*LENGTH`

Results in a Number Value that is the number of characters (not bytes) in the Text object.

`Returns:` num_at

`*LE` (text_t s)

Results in Boolean TRUE value if the Text object is less than or equal to the input argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*LOCATION_LONG`

Get the location qualifier from CLIENT.IP.SRC.LOCATION.GET(n) (ISO short name) and then convert it to human readable long name. This conversion is valid only for country names. Correct Country qualifier value (number) in GET(n) is left up to the user as qualifiers are user configurable. Expression example: CLIENT.IP.SRC.LOCATION.GET(1).LOCATION_LONG For example: Data

from each expression CLIENT.IP.SRC.LOCATION: NA.US.California.SantaClara.*.* CLIENT.IP.SRC.LOCATION.GET(1): US CLIENT.IP.SRC.LOCATION.GET(1).LOCATION_LONG: United States

`Returns:` text_t

`*LT` (text_t s)

Results in Boolean TRUE value if the Text object is less than the input argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*MAP_STRING_DEFAULT_TO_KEY` (text_t string_map_name)

Returns the value corresponding to the key in the string map. This is similar to the MAP_STRING method, but if the key is not present then instead of returning a null string, it returns the key itself. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed)`:`

string_map_name- identifies the string map.

`Returns:` text_t

`*MAP_STRING` (text_t string_map_name)

Returns value corresponding to key in the string map. Key is the string that it is given as input. Text mode IGNORECASE, NOIGNORECASE - controls whether key lookup in string map is case sensitive or not. For example:

- HTTP.REQ.URL.MAP_STRING("url_stringmap") returns value when the value of HTTP.REQ.URL is used as key in the string map whose name is "url_stringmap".
- HTTP.REQ.URL.SET_TEXT_MODE(IGNORECASE). MAP_STRING("url_stringmap") returns value when the value of HTTP.REQ.URL is used as key in the string map whose name is "url_stringmap". Key lookup in this case is done case-insensitively.

`Parameters` (expressions not allowed)`:`

string_map_name- identifies the string map.

`Returns:` text_t

`*MARK_SAFE`

Mark the PIXL expression safe without applying any safe transform.

`Returns:` text_t

`*MAX` (text_t s)

Compares the string argument with the current string and returns the max string. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*MIN` (text_t s)

Compares the string argument with the current string and returns the min string. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*NE` (text_t s)

Results in Boolean TRUE value if the Text object is not equal to the input argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*NORMALIZE_URL`

Normalize URL. Normalizes a URL by doing "percent" decoding. See the description for URLENCODED in the SET_TEXT_MODE function. This performs the equivalent of

SET_TEXT_MODE(URLENCODED).DECODE_USING_TEXT_MODE, except that it does not change the value of the current text mode.

`Returns:` text_t

`*PKEY_ENCRYPT_PEM_NO_PADDING` (text_t pem_pkey)

Encrypts the input text using the RSA public key provided by the PEM string and RSA_NO_PADDING padding method. The input text to be encrypted cannot be longer than the public key length minus 11 bytes for padding. For example, for a 1024-bit (128 byte) key, the input text cannot be longer than 128 - 11 = 117 bytes. An Undef error will occur if the input text is too long. A null input will also cause an Undef error. Returns the (unencoded binary) encrypted text, which is typically base-64 encoded for use in a message.

`Parameters``:`

pem_pkey- a text expression that supplies a RSA public key in the PEM format. If the text value is not a valid PEM RSA PUBLIC KEY encoding, an Undef error will occur. Example (a 1024-bit public key):

```
"-----BEGIN RSA PUBLIC KEY-----" +

"MIGJAoGBAKl5vgQEj73Kxp+9yn1v5gPR1pnc4oLM2a0kaWwBOsB6rzCIy6znwnvw" +

"CY1xRvQhRlJSAyJbloL7wZFIJ2FOR8Cz+8ZQWXU2syG+udi4EnWqLgFYowF9zK+o" +

"79az597eNPAjsHZ/C2oL/+6qY5a/f1z8bQPrHC4GpFfAEJhh/+NnAgMBAAE=" +

"-----END RSA PUBLIC KEY-----"
```

`Returns:` text_t

`*PKEY_ENCRYPT_PEM` (text_t pem_pkey)

Encrypts the input text using the RSA public key provided by the PEM string and the RSA_PKCS1_PADDING padding method. The input text to be encrypted cannot be longer than the public key length minus 11 bytes for padding. For example, for a 1024-bit (128 byte) key, the input text cannot be longer than 128 - 11 = 117 bytes. An Undef error will occur if the input text is too long. A null input will also cause an Undef error. Returns the (unencoded binary) encrypted text, which is typically base-64 encoded for use in a message.

`Parameters``:`

pem_pkey- a text expression that supplies a RSA public key in the PEM format. If the text value is not a valid PEM RSA PUBLIC KEY encoding, an Undef error will occur. Example (a 1024-bit public key):

```
"-----BEGIN RSA PUBLIC KEY-----" +

"MIGJAoGBAKl5vgQEj73Kxp+9yn1v5gPR1pnc4oLM2a0kaWwBOsB6rzCIy6znwnvw" +

"CY1xRvQhRlJSAyJbloL7wZFIJ2FOR8Cz+8ZQWXU2syG+udi4EnWqLgFYowF9zK+o" +

"79az597eNPAjsHZ/C2oL/+6qY5a/f1z8bQPrHC4GpFfAEJhh/+NnAgMBAAE=" +

"-----END RSA PUBLIC KEY-----"
```

`Returns:` text_t

`*PKEY_SIGN_CERTKEY` (text_t certkey_name)

Generates a binary digital signature using the SHA-256 message digest function and an RSA private key from the specified SSL certKey object.

`Parameters``:`

certkey_name- identifies the configured certKey object. Results in an Undef error if the certkey object does not exist or does not contain an RSA private key, or if the signing operation cannot complete.

`Returns:` text_t

`*PKEY_SIGN_XML` (text_t xml_pkey)

Generates a binary digital signature using the SHA-256 message digest function and an RSA private key from the specified XML element.

`Parameters``:`

xml_pkey- an expression that supplies an <RSAKeyValue> element with the private key. Example: <RSAKeyValue> <Modulus>qXm+BASPvcrGn73KfW/
mA9HWmdzigszZrSRpbAE6wHqvMIjLrOfCe/
AJjXFG9CFGUlIDIluWgvvBkUgnYU5HwLP7xlBZdTazIb652LgSdaouAVijAX3Mr6jv1rPn3t408COwdn8Lagv/
7qpjlr9/XPxtA+scLgakV8AQmGH/42c=</Modulus> <Exponent>AQAB</Exponent>"zNjysxcIJV/
J9cTpIgPp2/x1IXHT5GTH8OMuNad0qtRSLjU1QYUmmkm9QcJJAN+7h8FEXWGabySUzBrHj/

IEbw==" <DP>QavUDQLLQpnPJXtVAo6CYhxOMCd68mwTxYKKNLjmC0pd54SFHllTLPE1FZU5EjK6q3nCeijonpfH+XX DP> <DQ>EiXOKouJzzXTQJC3TqomF7Uf81yQNxWumOqnd11kepXgyfMwyqMvLlAGEkNSEF/ Bz18R3Wv+MIZ/IC3nLBt2xQ==</DQ> <InverseQ>ocuCmz36CP+N2aGqxaU+BKD5+3RLgRq9LFhULEz2jKx0iV9r76jsAxn3sLcTYYO9eqRPy2cz74AU nw==</InverseQ> <D>fTBD773a3GzcmgVdfZlaBLpN1ux2mf5uUVrTUQf7eVFm9egm4/ tzC5A9zjC+I/oscwTH8epL3UfRLdtp05Q6pWfJBXEnGo0QmOFFBK4pLx/ 5JJpPGZ69ovDFEVOUHyiCfKE/g97T4WX3us0nFe1272zwGlHarM1YYwvfeE08UdE=</D> </ RSAKeyValue> Results in an Undef error if the XML element is invalid or does not correctly specify an RSA private key, or if the signing operation cannot complete.

`Returns:` text_t

`*PKEY_VERIFY_CERTKEY` (text_t certkey_name, text_t signature)

Verifies if the input text matches the specified signature generated using the SHA-256 messge digest function and the RSA private key associated with the specified RSA public key in the X.509 certificate in the specified certKey object. Returns true if the signature is verified, false otherwise.

`Parameters``:`

certkey_name- identifies the certkey object containing an X.509 certificate holding the RSA public key.

signature- the binary signature. Results in an Undef error if the certkey object does not exist or does not contain an X.509 certificate with an RSA public key, or if the verification operation cannot complete.

`Returns:` bool_at

`*PKEY_VERIFY_XML` (text_t xml_pkey, text_t signature)

Verifies if the input text matches the specified signature generated using the SHA-256 messge digest function and the RSA private key associated with the RSA public key supplied by the specified XML element. Returns true if the signature is verified, false otherwise.

`Parameters``:`

xml_pkey- an expression that supplies an <RSAKeyVAlue> element with the public key. Example: <RSAKeyValue> <Modulus>qXm+BASPvcrGn73KfW/ mA9HWmdzigszZrSRpbAE6wHqvMIjLrOfCe/ AJjXFG9CFGUlIDIluWgvvBkUgnYU5HwLP7xlBZdTazIb652LgSdaouAVijAX3Mr6jv1rPn3t408COwdn8Lagv/

7qpjlr9/XPxtA+scLgakV8AQmGH/42c=</Modulus> <Exponent>AQAB</Exponent> </RSAKeyValue>

signature- the binary signature. Results in an Undef error if the XML element is invalid or does not correctly specify an RSA public key, or if the verification operation cannot complete.

`Returns:` bool_at

`*PREFIX` (`char` c, `uint` i)

Select a prefix of the Text. The selected prefix is the longest prefix that has at most Count (2nd argument) occurrences of character in the 1st argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

c- Character

i- Count

`Returns:` text_t

`*PREFIX` (`uint` i)

Select a prefix of the Text. The length of the prefix is equal to the number in the argument. If there aren't enough characters in the Text object then the entire Text is selected.

`Parameters``:`

i- Prefix Length

`Returns:` text_t

`*REGEX_REPLACE` (`re` regex, text_t replacement, replacemode_e mode)

Selects the text that matches the given regular expression argument and replaces it with the the text given in the second argument. The third argument specifies whether the first match is only replaced when multiple matches occur in the text or all matches are replaced. The match may occur anywhere within the text - if you wish to "anchor" this, use "\^" at the start of the regex and/or "$" at the end of the regex. When the regular expression does not match the given string then the same string is returned.

For example: HTTP.RES.BODY(999).REGEX_REPLACE(re!\\bpassword:\\s*\\b!, "password: ***", ALL) will replace all occurrences of "password:" with "password: ***" This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

regex- Regular Expression

replacement- String to replace the match

mode- Mode of replacement

`Returns:` text_t

`*REPEAT` (`uint` i)

Produces a string which contains 'i' sequential copies of the input string.

`Parameters``:`

i- the number of times to repeat the string (0 or more)

`Returns:` text_t

`*SET_CHAR_SET` (charset_e charset)

Set the character set to use for subsequent functions that use text.

`Parameters` (expressions not allowed) `:`

charset- Character Set

`Returns:` http_header_t

`*SET_TEXT_MODE` (textmode_e mode)

The mode setting of a Text object controls the behavior of many Text operations. The Text mode settings may also control the behavior of some operations in objects (like List) that build upon the Text object. IGNORECASE, NOIGNORECASE - controls whether string comparison is case sensitive or not. URLENCODED - If set then all Text operations are carried out after translating all %HH or %uHHHH encodings in the underlying byte stream. 1. %HH will be translated to the character Y where HH denotes the ascii value of character Y in hexadecimal. For example, the encoded text "http%3a/.html" will be decoded to "http:/.html" 2. %uWWHH will be translated to the character sequence YZ where WW denotes the ascii value of character Y in hexadecimal and HH

denotes the ascii value of character Z in hexadecimal. For example, the encoded text "http%u3a2f.html" and "http%u003a/.html" will both be decoded to"http:/.html" NOURLENCODED - Indicates that no percent encodings are present in the Text object. No percent decoding will be performed on the Text object. PLUS_AS_SPACE - If set then all Text operations are carried out after converting occurrences of the plus character to whitespace. For example, the text "hello+world" will be decoded to "hello world" NO_PLUS_AS_SPACE - If set, then the plus character will not be converted to whitespace in the Text object. BACKSLASH_ENCODED - If set, then all Text operations are carried out after performing the following operations: 1. \\XXX will be translated to the character Y where XXX denotes the ascii value of character Y in octal. The valid range of octal values for this type of encoding is \\0 to \\377. For example, the encoded text "http\ \72/.html" and "http\\072/.html" will both be decoded to "http:/.html" 2. \\xHH will be translated to the character Y where HH denotes the ascii value of character Y in hexadecimal. For example, the encoded text "http\\x3a/.html" will be decoded to "http:/.html" 3. \\\\uWWXX will be translated to the character sequence YZ where WW denotes the ascii value of character Y in hexadecimal and XX denotes the ascii value of character Z in hexadecimal. For example, the encoded text "http%u3a2f.html" and "http%u003a/.html" will both be decoded to"http:/.html" 4. Occurences of "\ \b", "\\n", "\\t", "\\f" and "\\r" are translated to the corresponding ascii characters. NO_BACKSLASH_ENCODED - If set, then backslash decoding will not be performed on the Text object. BAD_ENCODE_RAISE_UNDEF - If set, then UNDEF is raised if either the URLENCODED or BACKSLASH_ENCODED mode is set and a bad encoding corresponding to the specified encoding mode is encountered. NO_BAD_ENCODE_RAISE_UNDEF - If set, then UNDEF will not be raised when a bad encoding is encountered in the Text object. The Text operations operate on characters (as opposed to operating on bytes). By default a single byte represents a character using the ASCII encoding. But if URLENCODED mode is set then 3 bytes may represent a character. A PREFIX(3) operation will select the first 3 characters in the Text object. That means it may select up to 9 bytes for URLENCODED Text object. In the case of multibyte decodings as a result of %uXXXX or \\\\uXXXX, Text operations which attempt to treat the multiple decoded bytes as distinct characters are not allowed.

`Parameters` (expressions not allowed) `:`

mode- Text Mode

`Returns:` http_header_t

`*SKIP` (`char` c, `uint` i)

Select the Text after skipping over a prefix of the current Text. The skipped over prefix is the longest prefix that has at most Count (2nd argument) occurrences of character in the 1st argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

c- Character

i- Count

`Returns:` text_t

`*SKIP` (`uint` i)

Select the Text after skipping over a prefix in the current Text. The length of the prefix is equal to the number in the argument. If there aren't enough characters in the Text object then the entire Text is skipped over.

`Parameters` (expressions not allowed) `:`

i- Prefix Length

`Returns:` text_t

`*STARTSWITH_ANY` (text_t patset_name)

Results in Boolean TRUE value if the Text starts with any of the strings that are bound to the patset or dataset named by the string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` bool_at

`*STARTSWITH_INDEX` (text_t patset_name)

Returns the numerical index of the matching string, if the Text starts with any of the strings that are bound to the patset or dataset named by the string argument. Returns 0 if there is no match. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` num_at

`*STARTSWITH` (text_t start)

Results in Boolean TRUE value if a prefix of the Text object matches the string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

start- String

`Returns:` bool_at

`*STRIP_CHARS` (text_t s)

From the selected text remove the characters specified in the string.

For example: Say the selected text is / "foo.xyz=bar" /. Then on executing STRIP_CHARS('.=') or STRIP_CHARS('..=') the selected text will become /fooxyzbar /. Note that repeating character has same effect as it would be if it present only once. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*STRIP_END_CHARS` (text_t s)

Selects the Text after stripping off characters in the end of the current Text object.

For example: Say the selected text is / "foo.xyz=bar" /. Then on executing STRIP_END_CHARS('ar') the selected text will become /foo.xyz=b /. Note that repeating character has same effect as it would be if it present only once. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*STRIP_END_WS`

Selects the Text after stripping off white space in the end of the current Text object.

`Returns:` text_t

`*STRIP_START_CHARS` (text_t s)

Selects the Text after stripping off characters in the beginning of the current Text object.

For example: Say the selected text is / "foo.xyz=bar" /. Then on executing STRIP_START_CHARS('of') the selected text will become /.xyz=bar /. Note that repeating character has same effect as it would be if it present only once. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*STRIP_START_WS`

Selects the Text after stripping off white space in the beginning of the current Text object.

`Returns:` text_t

`*SUBSTR_ANY` (text_t patset_name)

Select any one sub-string that matches any string in the given patset or dataset. The patset cannot have strings longer than 255 characters. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` text_t

`*SUBSTR` (`uint` start, `uint` len)

Select the Text object of the given length at the given offset. Offset it 0 based. If there aren't enough characters after the offset then all the remaining characters are selected.

`Parameters``:`

start- Offset

len- Length

`Returns:` text_t

`*SUFFIX` (`char` c, `uint` i)

Select a suffix of the Text. The selected suffix is the longest possible suffix containing at most Count (2nd arg) occurrences of the character in the 1st argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

c- Character

i- Count

`Returns:` text_t

`*SUFFIX` (`uint` i)

Select a suffix of the Text. The length of the suffix is equal to the number in the argument. If there aren't enough characters in the Text object then the entire Text is selected.

`Parameters``:`

i- Suffix Length

`Returns:` text_t

`*TO_LOWER`

Converts the selected text to lower case.

For example, the string "ABCd" is converted to "abcd"

`Returns:` text_t

`*TO_UPPER`

Converts the selected text to upper case.

For example, the string "abcD" is converted to "ABCD"

`Returns:` text_t

`*TRUNCATE` (`char` c, `uint` i)

Select the Text after truncating a suffix from the current Text object. The truncated suffix is the longest possible suffix containing at most Count (2nd arg) occurrences of the character in the 1st argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

c- Character

i- Count

`Returns:` text_t

`*TRUNCATE` (`uint` i)

Select the Text after truncating a suffix of the Text. The length of the suffix truncated is equal to the number in the argument. If there aren't enough characters in the Text then then all the characters are truncated.

`Parameters``:`

i- Suffix Length

`Returns:` text_t

`*TYPECAST_AVP_T`

Convert text_t to avp_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (avp_t : Operations that can be performed on the returned AVPs.

`Note:` An AVP can have multiple instances in a Diameter message. However, the system can access only the first 16 instances.

`Example:`

- To get the first value of AVP code 266 from a request, use: DIAMETER.REQ.AVP(266).VALUE(0).
- To get the fourth value of AVP code 266 from a request, use: DIAMETER.REQ.AVP(266).VALUE(3).
- To check if AVP code 1000 in the response has the vendor-specific bit set, use: DIAMETER.RES.AVP(1000).IS_VENDOR_SPECIFIC.

)

`Returns:` avp_t

`*TYPECAST_AVP_UNUM_T`

Convert text_t to avp_unum_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (avp_unum_t : In Diameter AVP based expressions can be written as DIAMETER.REQ.AVP(<avpcode>). For example Auth-Application-Id AVP (AVP code 258) can be extracted as DIAMETER.REQ.AVP(258) For few of the important AVPs we provide aliases. For example this AVP based expression can also be written as DIAMETER.REQ.AUTH_APPLICATION_ID. This expression returns either a object of class avp_t or returns a numerical value (object of class unsigned_long_at). The numerical value for this object is derived from the value in first instance of the AVP.)

`Returns:` avp_unum_t

`*TYPECAST_BOOL_AT`

Convert text_t to bool_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (bool_at : Boolean Operations)

`Returns:` bool_at

`*TYPECAST_COOKIE_T`

Convert text_t to cookie_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (cookie_t : The HTTP Cookie type provides operations for a cookie as it appears in the Set-Cookie and Set-Cookie2 header. In this type the Name-Value List operations are also available. The first delimiter is = and the element delimiter is ;. Multiple consecutive ; are treated as one. (Same as applying the method IGNORE_EMPTY_ELEMENTS on a Name-Value List.) You can use the Name-value List operations to access cookie attributes. The name comparison for all list operations is case insensitive. In this type Text operations are also available. Each cookie begins with a COOKIE_NAME=COOKIE_VALUE pair followed by zero or more semi-colon separated attribute-value pairs. If an attribute appears more than once in a cookie, the value associated with the first appearance of the attribute is returned.

Format Cookie: Cookie1=Value;Version=decimal;Value;Domain=Value;Path=Value)

`Returns:` cookie_t

`*TYPECAST_DIAMETER_FLAG_T`

Convert text_t to diameter_flag_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (diameter_flag_t : Provides operation to treat the underlying 1 byte as set of bit flags. then set/unset/test/reset_all operations can be done on flag)

`Returns:` diameter_flag_t

`*TYPECAST_DNS_DOMAINNAME_T`

Convert text_t to dns_domainname_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (dns_domainname_t : This object provides operations for parsing the DNS domain name as it appears at various places in the DNS data. The format is abc.foo.com.)

`Returns:` dns_domainname_t

`*TYPECAST_DNS_FLAG_T`

Convert text_t to dns_flag_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (dns_flag_t : Provides operations to test/set/unset a flag in dns header.)

`Returns:` dns_flag_t

`*TYPECAST_DOUBLE_AT`

Convert text_t to double_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_at : Double Value)

`Returns:` double_at

`*TYPECAST_DOUBLE_T` (double_format_e format)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error.)

`Parameters` (expressions not allowed) `:`

format- Format

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, double_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, ip_address_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, num_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one

or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, time_local_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, time_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, unsigned_long_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_HTTP_CACHE_CONTROL_T`

Convert text_t to http_cache_control_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_cache_control_t : This object provides for the ability to work on HTTP Cache-Control headers. The name comparison for all list operations is case insensitive.)

`Returns:` http_cache_control_t

`*TYPECAST_HTTP_CONTENT_LENGTH_T`

Convert text_t to http_content_length_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_content_length_t : The HTTP.REQ.CONTENT_LENGTH or HTTP.RES.CONTENT_LENGTH object can be treated as a HTTP Header or as a Number. The numerical value for this object is derived from the value in the last instance of the Content-Length header.)

`Returns:` http_content_length_t

`*TYPECAST_HTTP_COOKIE_T`

Convert text_t to http_cookie_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_cookie_t : This object provides operations for parsing

the HTTP cookie header. The name-value pair is derived from the value in the last instance of Cookie header. The format is Cookie : name0=value0; name1=value1; An HTTP Cookie header can have multiple occurrences. COUNT will return a Number containing how many headers of the current type exist. The name comparison for all list operations is case insensitive. The system does not keep track of more than 15 HTTP headers. The result will be undefined if there are more than 15 instances of the header.)

`Returns:` http_cookie_t

`*TYPECAST_HTTP_DATE_T`

Convert text_t to http_date_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_date_t : The HTTP.REQ.DATE or HTTP.RES.DATE object can be treated as a HTTP header or a Time object. The Time value is derived from the value in the last instance of the Date header. The date formats supported are RFC 822 (updated by RFC 1123), RFC 1036 (obsoletes RFC850) and ANSI C asctime() formats.)

`Returns:` http_date_t

`*TYPECAST_HTTP_HEADER_T` (text_t name)

Convert text_t to http_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_header_t : When typecasting a Text object to HTTP Header a header name must be provided.For example: HTTP.REQ.HEADER("MyHdr").TYPECAST_HTTP_HEADER_T("InHdr"))

`Parameters` (expressions not allowed) `:`

name- Header Name

`Returns:` http_header_t

`*TYPECAST_HTTP_HOSTNAME_T`

Convert text_t to http_hostname_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_hostname_t : This object provides operations for parsing the HTTP hostname as it appears at various places in the HTTP protocol data. The format is abc.foo.com:8080.)

`Returns:` http_hostname_t

`*TYPECAST_HTTP_METHOD_T`

Convert text_t to http_method_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_method_t : This object provides Text operations and HTTP Request Method Enum operations on the HTTP request method.)

`Returns:` http_method_t

`*TYPECAST_HTTP_SET_COOKIE_T`

Convert text_t to http_set_cookie_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_set_cookie_t : HTTP.RES.SET_COOKIE provides operations for parsing and operating on the SET-COOKIE header that is present in the HTTP response. HTTP Set-Cookie header supports Text and HTTP Header operations. For most Text operations the value in the last Set-Cookie header is selected. HTTP Set-Cookie header also supports special operations to extract cookies from the response. It is assumed that there will be only one cookie in a Set-Cookie header.)

`Returns:` http_set_cookie_t

`*TYPECAST_HTTP_URL_T`

Convert text_t to http_url_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_url_t : HTTP.REQ.URL provides operations for parsing and operating on the URL that is present in the first line of the HTTP request header. The supported format is \[<protocol>://<hostname>\]<path>?<query>. The Text object backing a HTTP URL object has the Text Mode set to URLENCODED by default.)

`Returns:` http_url_t

`*TYPECAST_HTTP_VERSION_T`

Convert text_t to http_version_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_version_t : HTTP.REQ.VERSION or HTTP.RES.VERSION provide operations to extract HTTP version information.)

`Returns:` http_version_t

`*TYPECAST_IPV6_ADDRESS_AT`

Convert text_t to ipv6_address_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ipv6_address_at : Provides operations for the 128-bit IPv6 address value. Some general information regarding IPv6 expressions: IPv6 PIXL expressions can be combined with other PIXL expressions using the '+' operator. The output is expected to be

the concatenation of the string representations of the individual PIXL expressions. No other operator other than '+' is expected to work when any of the operands is an IPv6 PIXL expression. Also, IPv6 PIXL expressions can be combined with any other type of PIXL expression except a PIXL expression that produces a bool result. In other words, if A and/or B are two IPv6 addresses, A+B should result in the string AB. When one of A or B is an IPv6 address, the other can only be a number or a string and not a boolean. Further, when A and/or B is an IPv6 address, the only operator allowed between them is '+'.

Example: Let the client source IPv6 address be ABCD:1234::ABCD. Let the server destination IPv4 address be 10.100.10.100. Then the expression CLIENT.IPV6.SRC + SERVER.IP.DST should produce the output "ABCD:1234::ABCD10.100.10.100". Similarly, CLIENT.IPV6.SRC + 5 should produce the result ABCD:1234::ABCD5)

`Returns:` ipv6_address_at

`*TYPECAST_IPV6_ADDRESS_T`

Convert text_t to ipv6_address_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ipv6_address_t : This object represents an IPv6 address present in the 1000:1001:CD10:0000:0000:89AB:4567:CDEF format.)

`Returns:` ipv6_address_t

`*TYPECAST_IPV6_SUBNET_AT`

Convert text_t to ipv6_subnet_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ipv6_subnet_at : Provides operations for the integral IPv6 subnet address value.)

`Returns:` ipv6_subnet_at

`*TYPECAST_IPV6_SUBNET_T`

Convert text_t to ipv6_subnet_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ipv6_subnet_t : This object represents an IPv6 subnet address present in the 1000:1001:CD10:0000:0000:89AB:4567:CDEF/64 format.)

`Returns:` ipv6_subnet_t

`*TYPECAST_IP_ADDRESS_AT`

Convert text_t to ip_address_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ip_address_at : Provides operations for the 32-bit integral IP address value.)

`Returns:` ip_address_at

`*TYPECAST_IP_ADDRESS_T`

Convert text_t to ip_address_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ip_address_t : Represents an IP address present in the 10.100.200.1 format.)

`Returns:` ip_address_t

`*TYPECAST_IP_OPTIONS_T`

Convert text_t to ip_options_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ip_options_t : IP protocol options)

`Returns:` ip_options_t

`*TYPECAST_IP_OPTIONS_TYPE_T`

Convert text_t to ip_options_type_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ip_options_type_t : IP Options Type)

`Returns:` ip_options_type_t

`*TYPECAST_IP_TOS_T`

Convert text_t to ip_tos_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ip_tos_t : Provides operations to TOS field in IP header.)

`Returns:` ip_tos_t

`*TYPECAST_LIST_T` (`char` sep)

Convert text_t to list_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (list_t : The character separator has to be provided when typecasting a textual context to list type. The current text mode has no effect on the character separator. For example if the current text mode is IGNORECASE and the separator is p then P will not be treated as a separator.)

`Parameters` (expressions not allowed) `:`

sep- Separator

`Returns:` list_t

`*TYPECAST_MAC_ADDRESS_AT`

Convert text_t to mac_address_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (mac_address_at : Provides operations for the 48-bit MAC address value.)

`Returns:` mac_address_at

`*TYPECAST_MAC_ADDRESS_T`

Convert text_t to mac_address_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (mac_address_t : Represents a MAC address present in the 12:34:56:78:9a:bc format.)

`Returns:` mac_address_t

`*TYPECAST_NUM_AT`

Convert text_t to num_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (num_at : Number Value)

`Returns:` num_at

`*TYPECAST_NUM_T` (num_format_e format)

Convert text_t to num_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (num_t : Treat the underlying text as a Number in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error.)

`Parameters` (expressions not allowed) `:`

format- Format

`Returns:` num_t

`*TYPECAST_NUM_T` (num_format_e format, num_at default_value)

Convert text_t to num_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (num_t : Treat the underlying text as a Number in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` num_t

`*TYPECAST_NVLIST_T` (`char` sep1, `char` sep2)

Convert text_t to nvlist_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (nvlist_t : Two character delimiters have to be provided when typecasting a Text object to a Name-Value List. The first delimited separates the name from the value. The second delimiter separates list items. For example typecast_nvlist_t('=', '&') handles a URL query string. The Text Mode has no effect on the character delimiters. For example if the current text mode is IGNORECASE and a delimiter is p then P will not be treated as a delimiter.)

`Parameters` (expressions not allowed) `:`

sep1- delimiter1

sep2- delimiter2

`Returns:` nvlist_t

`*TYPECAST_NVLIST_T` (`char` sep1, `char` sep2, `char` quote)

Convert text_t to nvlist_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (nvlist_t : Two character delimiters and quote-character have to be provided when typecasting a Text object to a Name-Value List that supports quote-character. The first delimited separates the name from the value. The second delimiter separates list items. The third value specifies the quote character. For example typecast_nvlist_t('=', ';', "") handles a name-value list separated by semi-colons that allows quoting. The quote-character specifies that the

value can occur within the quotes and the delimiters within the quote-characters should not be taken into account. The Text Mode has no effect on the character delimiters. For example if the current text mode is IGNORECASE and a delimiter is p then P will not be treated as a delimiter.)

`Parameters` (expressions not allowed) `:`

sep1- delimiter1

sep2- delimiter2

quote- quote-character.

`Returns:` nvlist_t

`*TYPECAST_PROTOCOL_BUFFER_T`

Convert text_t to protocol_buffer_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (protocol_buffer_t : gRPC Protocol Buffers interface)

`Returns:` protocol_buffer_t

`*TYPECAST_RADIUS_AVP_T`

Convert text_t to radius_avp_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (radius_avp_t : Operations that can be performed on the returned AVPs.

`Note:` An AVP can have multiple instances in a radius message. However, the system can access only the first 16 instances.

`Example:`

- To get the first value of AVP code 26 from a request, use: radius.REQ.AVP(26).VALUE(0).
- To get the fourth value of AVP code 26 from a request, use: radius.REQ.AVP(26).VALUE(3).

)

`Returns:` radius_avp_t

`*TYPECAST_RADIUS_AVP_VALUE_T`

Convert text_t to radius_avp_value_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (radius_avp_value_t : Provides operations to typecast RADIUS AVP value to Integer value or IP Address.)

`Returns:` radius_avp_value_t

`*TYPECAST_SEQ_TEXT_T`

Convert text_t to seq_text_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (seq_text_t : Represents the Text Sequence class.)

`Returns:` seq_text_t

`*TYPECAST_SERVICEPATH_T`

Convert text_t to servicepath_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (servicepath_t : Operations that can be performed on the service path.

`Example:`

- To get the name of the service path applicable to current subscriber, use: SUBSCRIBER.SERVICEPATH
- To determine If the service function is the next in the service path applicable to scubscriber, use: SUBSCRIBER.SERVICEPATH.IS_NEXT().

)

`Returns:` servicepath_t

`*TYPECAST_SIP_CALLID_HEADER_T`

Convert text_t to sip_callid_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_callid_header_t : This object provides operations for parsing the SIP callid header.)

`Returns:` sip_callid_header_t

`*TYPECAST_SIP_CONTENT_LENGTH_T`

Convert text_t to sip_content_length_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_content_length_t : The SIP.REQ.CONTENT_LENGTH or SIP.RES.CONTENT_LENGTH object can be treated as a SIP Header or as a Number. The numerical value for this object is derived from the value in the last instance of the Content-Length header.)

`Returns:` sip_content_length_t

`*TYPECAST_SIP_FROM_HEADER_T`

Convert text_t to sip_from_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_from_header_t : This object provides operations for parsing the SIP From header.)

`Returns:` sip_from_header_t

`*TYPECAST_SIP_HEADER_T` (text_t name)

Convert text_t to sip_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_header_t : When typecasting a Text object to SIP Header a header name must be provided.For example: SIP.REQ.HEADER("MyHdr").TYPECAST_SIP_HEADER_T("InHdr"))

`Parameters` (expressions not allowed) `:`

name- Header Name

`Returns:` sip_header_t

`*TYPECAST_SIP_HOSTNAME_T`

Convert text_t to sip_hostname_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_hostname_t : This object provides operations for parsing the SIP hostname as it appears at various places in the SIP protocol data. The format is abc.foo.com:5060.)

`Returns:` sip_hostname_t

`*TYPECAST_SIP_METHOD_T`

Convert text_t to sip_method_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_method_t : This object provides Text operations and SIP Request Method Enum operations on the SIP request method.)

`Returns:` sip_method_t

`*TYPECAST_SIP_TO_HEADER_T`

Convert text_t to sip_to_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_to_header_t : This object provides operations for parsing the SIP From header.)

`Returns:` sip_to_header_t

`*TYPECAST_SIP_URL_T`

Convert text_t to sip_url_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_url_t : SIP.REQ.URL provides operations for parsing and operating on the URL that is present in the first line of the SIP request header. The supported format is \[<protocol>://<hostname>\]<path>?<query>. The Text object backing a SIP URL object has the Text Mode set to URLENCODED by default.)

`Returns:` sip_url_t

`*TYPECAST_SIP_VERSION_T`

Convert text_t to sip_version_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_version_t : SIP.REQ.VERSION or SIP.RES.VERSION provide operations to extract SIP version information.)

`Returns:` sip_version_t

`*TYPECAST_SIP_VIA_HEADER_T`

Convert text_t to sip_via_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_via_header_t : This object provides operations for parsing the SIP Via header.)

`Returns:` sip_via_header_t

`*TYPECAST_SSLVPN_MODE_T`

Convert text_t to sslvpn_mode_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sslvpn_mode_t : This object provides Text operations and SSLVPN Mode Enum operations on the SSLVPN request method.)

`Returns:` sslvpn_mode_t

`*TYPECAST_SSL_TEXT_T` (text_t name)

Convert text_t to ssl_text_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ssl_text_t : Treat the underlying text object as SSL Text.)

`Parameters` (expressions not allowed) `:`

name- Name

`Returns:` ssl_text_t

`*TYPECAST_TCP_OPTIONS_T`

Convert text_t to tcp_options_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (tcp_options_t : TCP Protocol Options)

`Returns:` tcp_options_t

`*TYPECAST_TCP_OPTIONS_TYPE_T`

Convert text_t to tcp_options_type_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (tcp_options_type_t : TCP Protocol Options Type)

`Returns:` tcp_options_type_t

`*TYPECAST_TCP_REPEATER_OPTION_T`

Convert text_t to tcp_repeater_option_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (tcp_repeater_option_t : TCP Protocol Option : Repeater)

`Returns:` tcp_repeater_option_t

`*TYPECAST_TIME_AT`

Convert text_t to time_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (time_at : Treats a number value as number of seconds since GMT Jan 1 1970 0h 0m 0s.)

`Returns:` time_at

`*TYPECAST_TIME_LOCAL_AT`

Convert text_t to time_local_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (time_local_at : Treats a number value as number of seconds since GMT Jan 1 1970 0h 0m 0s as adjsuted for the local time zone.)

`Returns:` time_local_at

`*TYPECAST_TIME_T`

Convert text_t to time_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (time_t : This object treats a Text object as a date string. The formats supported are

1\. RFC822 :: Sun, 06 Nov 1994 08:49:37 GMT 2\. RFC850 :: Sunday, 06-Nov-94 08:49:37 GMT 3\. ASCTIME :: Sun Nov 6 08:49:37 1994 4\. ASCTIME like :: Sun Nov 6 08:49:37 1994 5\. ASCTIME like :: Sun Nov 06 08:49:37 1994 6\. Http Set-Cookie Expiry date :: Sun, 06-Nov-1994 08:49:37 GMT)

`Returns:` time_t

`*TYPECAST_UNSIGNED_LONG_AT`

Convert text_t to unsigned_long_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_at : Unsigned Long(64bit) Value)

`Returns:` unsigned_long_at

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error.)

`Parameters` (expressions not allowed) `:`

format- Format

`Returns:` unsigned_long_t

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format, ip_address_at default_value)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining

characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` unsigned_long_t

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format, unsigned_long_at default_value)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` unsigned_long_t

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format, num_at default_value)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` unsigned_long_t

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format, time_local_at default_value)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` unsigned_long_t

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format, time_at default_value)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` unsigned_long_t

`*TYPECAST_UNUM_TEXT_T`

Convert text_t to unum_text_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unum_text_t : Provides operations to treat the underlying OctectString as Binary String or unsigned long value .)

`Returns:` unum_text_t

`*TYPECAST_URL_CATEGORY_T`

Convert text_t to url_category_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (url_category_t : Retrieves URL category and attributes from an URL)

`Returns:` url_category_t

`*TYPECAST_VENDOR_SPEC_APPID_AVP_T`

Convert text_t to vendor_spec_appid_avp_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (vendor_spec_appid_avp_t : Retrieves AVPs that are nested in the grouped AVP Vendor-Specific-Application-Id (code 260). The nested AVPs are:

- Vendor-Id
- Auth-Application-Id
- Acct-Application-Id

For example, to retrieve the Auth-Application-Id AVP from the Vendor-Specific-Application-Id AVP:

- For requests:
  DIAMETER.REQ.VENDOR_SPECIFIC_APPLICATION_ID.AUTH_APPLICATION_ID
- For responses:
  DIAMETER.RES.VENDOR_SPECIFIC_APPLICATION_ID.AUTH_APPLICATION_ID

)

`Returns:` vendor_spec_appid_avp_t

`*TYPECAST_VENDOR_SPEC_RADIUS_AVP_T`

Convert text_t to vendor_spec_radius_avp_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (vendor_spec_radius_avp_t :

- Vendor-Id

To retrieve the Vendor-Id from the Vendor-Specific AVP:

- RADIUS.REQ.VENDOR_SPECIFIC.VENDORID

)

`Returns:` vendor_spec_radius_avp_t

`*UNQUOTE` (`char` c)

If selected text is quoted by character c, Remove character c from beginning and end.

For example: Say the selected text is / "foo xyz bar " /. Then on executing UNQUOTE("") the selected text will become /foo xyz bar / This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

c- Character

`Returns:` text_t

`*URLSET_MATCHES_ANY` (text_t urlset_name)

Results in Boolean TRUE value if and only if the Text matches any of the patterns that are specified in the urlset named by the string argument. The matching is case-insensitive for domains, but case-sensitive for paths. For example:

- HTTP.REQ.HOST.APPEND(HTTP.REQ.URL).URLSET_MATCHES_ANY("urlset_forbidden") returns true when the combined domain and URL matches any pattern in the urlset whose name is "urlset_forbidden".

`Parameters` (expressions not allowed) `:`

urlset_name- urlset name

`Returns:` bool_at

`*URL_CATEGORIZE` (`uint` min_reputation, `uint` max_reputation)

Returns the URL category for the supplied URL with the given minimum and maximum reputation score. Where a score of 5 is most risky and 1 is least risky. If either score is set to 0, that bound would be ignored. By specifying the reputation scores, the function will returned the category with the highest score (most risky) based on the bounds. If there was an error getting the category or if the URL is invalid then it will result in an Undef error. For example: HTTP.REQ.HOST.APPEND(HTTP.REQ.URL).URL_CATEGORIZE(0, 0) returns value when the combined domain and URL is looked up for the URL category with the highest reputation score (most risky).

`Parameters` (expressions not allowed) `:`

min_reputation- Minimum reputation score of URL category

max_reputation- Maximum reputation score of URL category

`Returns:` url_category_t

`*URL_RESERVED_CHARS_SAFE`

Converts URL reserved characters to corresponding '%XX' values and retains the rest. This is a read only operation.

```
Based on RFC3986, following are considered URL unreserved characters:

    Alpha-numeric characters: a-z, A-Z, 0-9

    Hyphen and underscore: "-", "_"

    Dot: "."

    Tilde: "~"
```

The rest are converted to %XX encoding, 'XX' is the hex-based representation of the input character. If the requirement is to encode all but URL safe characters, please consider using HTTP_URL_SAFE method.

`Returns:` text_t

`*XML_DECRYPT` (text_t certKeyName)

Decrypt the selected content, which was encrypted using the W3C XML Encryption standard.

`Parameters` (expressions not allowed) `:`

certKeyName- identifies the certkey object containing the RSA private key to be used to decrypt the bulk encryption key in the selected EncryptedData element.

`Returns:` text_t

`*XML_ENCRYPT` (text_t certKeyName, encrypt_method_e method)

Encrypt the selected cleartext using the W3C XML Encryption standard.

`Parameters` (expressions not allowed) `:`

certKeyName- identifies the certkey object containing an X.509 certificate with the RSA public key to be used to encrypt the generated bulk encryption key. Note that the certKey object need not, and usually will not, include the associated RSA private key.

method- specifies the bulk encryption method (rc4, des3, aes128, aes192, or aes256) used to encrypt the content.

`Returns:` text_t

`*XML_ENCRYPT` (text_t certKeyName, encrypt_method_e method, `uint` flags)

Encrypt the selected cleartext using the W3C XML Encryption standard.

`Parameters` (expressions not allowed) `:`

certKeyName- identifies the certkey object containing an X.509 certificate with the RSA public key to be used to encrypt the generated bulk encryption key. Note that the certKey object need not, and usually will not, include the associated RSA private key.

method- specifies the bulk encryption method (rc4, des3, aes128, aes192, or aes256) used to encrypt the content.

flags- optional bit mask to specify optional elements in the EncryptedData element. These are hints to tell the receiver what private key to use to decrypt the bulk encryption key, providing information from the certKey's X.509 certificate.

- 1 - include a KeyName element with the certKeyName;
- 2 - include a KeyValue element with the RSA public key from the certificate;
- 4 - include an X509IssuerSerial element with the certificate serial number and issuer DN;
- 8 - include an X509SubjectName element with the certificate subject DN;
- 16 - include an X509Certificate element with the entire certificate;

`Returns:` text_t

`*XPATH_HTML_WITH_MARKUP` (`xpath_str` xpathex)

Applies an XPath expression to the DOM for an HTML document and returns the selected node-set or string, including markup like element tags. node-sets are converted to strings using the standard XPath string conversion routine. The selected portion of the document can be used as the target for rewrite actions.

Examples: HTTP.REQ.BODY(1000).XPATH_HTML_WITH_MARKUP(xp%//md/head/title%) returns the <title> element in the document's <head> This can be used in a rewrite action to replace or delete the <title> element.

`Parameters` (expressions not allowed) `:`

xpathex- XPath Expression

`Returns:` text_t

`*XPATH_HTML` (`xpath_bool` xpathex)

Applies an XPath expression to the DOM for an HTML document and a boolean value.

Examples: HTTP.RES.BODY(1000).XPATH_HTML(xp%boolean(/md/head/meta)%) returns true if the <meta> element exists as a child of <head> element.

`Parameters` (expressions not allowed) `:`

xpathex- XPath Expression

`Returns:` bool_at

`*XPATH_HTML` (`xpath_double` xpathex)

Applies an XPath expression to the DOM for an HTML document and a double value.

Examples: HTTP.RES.BODY(1000).XPATH_HTML(xp%number(//video/@height)%) returns the numeric value of the height attribute of the first <video> element.

`Parameters` (expressions not allowed) `:`

xpathex- XPath Expression

`Returns:` double_at

`*XPATH_HTML` (`xpath_str` xpathex)

Applies an XPath expression to the DOM for an HTML document and returns the selected node-set or string. node-sets are converted to strings using the standard XPath string conversion routine.

Examples: HTTP.REQ.BODY(1000).XPATH_HTML(xp%//img/@src%) returns the string value of the src attribute of the first

```

HTTP_HOSTNAME_T

This object provides operations for parsing the HTTP hostname as it appears at various places in the HTTP protocol data. The format is abc.foo.com:8080.

This topic lists the expressions that are provided by this class.

`*Note` *: Expressions with the * symbol are inherited / promoted from text_t

- `DOMAIN`

  Operate as Text on the Domain name part of the hostname. If the hostname is www.foobar.com or www.foobar.com:8080, then domain is foobar.com. This operation will return incorrect results if the hostname has an IP address. This method also sets the text mode to case-insensitive. So all text operations after this method will operate in a case-insensitive manner.

`Returns:` text_t

`*EQ` (text_t hostname)

Operates on the text contents of hostname. Results in Boolean TRUE value if the hostname matches the input argument. The comparison will be case-insensitive and if textmode is URLENCODED the hostname will be decoded before comparison. If hostname is www.foobar.com or www.foobar.com., then EQ(www.foobar.com) returns TRUE.

`Parameters``:`

hostname- Hostname

`Returns:` bool_at

`*PORT`

Operate as Number on the port part of the hostname. The string following and including the first : is considered the port value. Examples:

If the hostname is www.foo.com:8080 then the port is ":8080". If the hostname is www.foo.com: then the port is ":". If the hostname is www.foo.com then the port is "" and points to just after ".com".

When the numerical value in the port is missing then it assumes a default value of 80 or 443 (for HTTPS connections).

`Returns:` num_t

`*SERVER`

Operate as Text on the Server name part of the hostname. If the hostname is www.foobar.com or www.foobar.com:8080, then server is www.foobar.com. This method also sets the text mode to case-insensitive. So all text operations after this method will operate in a case-insensitive manner.

`Returns:` text_t

`*TYPECAST_TEXT_T`

Convert http_hostname_t to text_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (text_t : Designates any piece of text.)

`Returns:` text_t

`*AFTER_REGEX` (`re` regex)

Selects the text after the portion that matches the given regular expression argument. The first match is returned when multiple matches occur in the text. The match may occur anywhere within the text - if you wish to "anchor" this, use "\^" at the start of the regex and/or "$" at the end of the regex. When the regular expression does not match the given string, a Text object of length of 0 is returned.

Example: HTTP.REQ.HEADER("etag").AFTER_REGEX(re/KX/) will select "DAPPER" from "KXDAPPER". This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

regex- Regular Expression

`Returns:` text_t

`*AFTER_STR_ANY` (text_t patset_name)

Selects the Text that is present after the first occurrence of any of the strings that are bound to the patset named by the string argument. If there is no match to any of the strings bound to the patset in the current Text object then the result Text object has 0 length. The patset cannot have strings

longer than 255 characters. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` text_t

`*AFTER_STR` (text_t s)

Selects the Text that is present after the first occurrence of the string argument. If there is no match for the argument in the current Text then the result Text object has 0 length. The input string cannot be bigger than 255 characters. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*APPEND` (bool_at b)

Appends the given boolean's string representation to the current string.

`Parameters``:`

b- the boolean value to append.

`Returns:` text_t

`*APPEND` (double_at i)

Appends the given double's string representation to the current string.

`Parameters``:`

i- the double value to append.

`Returns:` text_t

`*APPEND` (ip_address_at addr)

Appends the given IPv4's string representation to the current string.

`Parameters``:`

addr- the IPv4 address to append.

`Returns:` text_t

`*APPEND` (num_at i)

Appends the given number's string representation to the current string.

`Parameters``:`

i- the number value to append.

`Returns:` text_t

`*APPEND` (time_local_at t)

Appends the given time's string representation to the current string.

`Parameters``:`

t- the time value to append.

`Returns:` text_t

`*APPEND` (time_at t)

Appends the given time's string representation to the current string.

`Parameters``:`

t- the time value to append.

`Returns:` text_t

`*APPEND` (unsigned_long_at i)

Appends the given unsigned long's string representation to the current string.

`Parameters``:`

i- the unsigned long value to append.

`Returns:` text_t

`*APPEND` (ipv6_address_at addr)

Appends the given IPv6's string representation to the current string.

`Parameters``:`

addr- the IPv6 address to append.

`Returns:` text_t

`*APPEND` (ipv6_subnet_at addr)

Appends the given IPv6 subnet's string representation to the current string.

`Parameters``:`

addr- the IPv6 subnet to append.

`Returns:` text_t

`*APPEND` (mac_address_at addr)

Appends the given MAC's string representation to the current string.

`Parameters``:`

addr- the MAC address to append.

`Returns:` text_t

`*APPEND` (text_t str)

Appends the given string to the current string.

`Parameters``:`

str- the string to append.

`Returns:` text_t

`*APPEND` (time_at t)

Appends the given time's string representation to the current string.

`Parameters``:`

t- the time value to append.

`Returns:` text_t

`*B64DECODE`

Decodes the selected text using base64 decoding.

For example, the string "TWFu" is converted to "Man"

`Returns:` text_t

`*B64ENCODE`

Encodes the selected text using base64 encoding.

For example, the string "Man" is converted to "TWFu"

`Returns:` text_t

`*BEFORE_REGEX` (`re` regex)

Selects the text before the portion that matches the given regular expression argument. The first match is returned when multiple matches occur in the text. The match may occur anywhere within the text - if you wish to "anchor" this, use "\^" at the start of the regex and/or "$" at the end of the regex. When the regular expression does not match the given string, a Text object of length of 0 is returned.

For example: HTTP.RES.HEADER("content-type").BEFORE_REGEX(re#/#) will select "text" from "text/plain". This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

regex- Regular Expression

`Returns:` text_t

`*BEFORE_STR_ANY` (text_t patset_name)

Selects the Text that is present before the first occurrence of any of the strings that are bound to the patset or datasetnamed by the string argument. If there is no match to any of the strings bound to the patset in the current Text object then the result Text object has 0 length. The patset cannot have strings longer than 255 characters. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` text_t

`*BEFORE_STR` (text_t s)

Selects the Text that is present before the first occurrence of the string argument. If there is no match for the argument in the current Text object then the result Text object has 0 length. The input string cannot be bigger than 255 characters. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*BETWEEN` (text_t start, text_t end)

Results in Boolean TRUE value if length of the Text object is greater than or equal to the sum of the Start and End argument lengths and if the prefix of the Text object matches the Start string argument and if the Suffix of the Text object matches the End string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

start- Start

end- End

`Returns:` bool_at

`*BIN_DECODE` (binary_encoding_e encoding)

Decode the encoded input into its original byte sequence. An incorrectly enooded input will result in an Undef error.

`Parameters` (expressions not allowed) `:`

encoding- specifies how the bytes are encoded.

`Returns:` text_t

`*BIN_ENCODE` (binary_encoding_e encoding)

Encode the input byte sequence. Note that BIN_ENCODE(hex_colons) is equivalent to BLOB_TO_HEX().

`Parameters` (expressions not allowed) `:`

encoding- specifies how the bytes are to be encoded.

`Returns:` text_t

`*BLOB_TO_HEX`

Convert to hexadecimal representation and select text.

For example, the byte string abc is converted to 61:62:63.

`Returns:` text_t

`*COMPARE` (text_t s)

Results in a Number Value which is the result of comparison of the input argument with the Text object. The result is greater than 0 if the Text object is lexicographically greater than the argument. The result is 0 if the Text object and the argument match. The result is less than 0 if the Text object is lexicographically lesser than the argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` num_at

`*CONTAINS_ANY` (text_t patset_name)

Results in Boolean TRUE value if the Text contains any of the strings that are bound to the patset or dataset named by the string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` bool_at

`*CONTAINS_INDEX` (text_t patset_name)

Returns the numerical index of the matching string, if the Text contains any of the strings that are bound to the patset or dataset named by the string argument. Returns 0 if there is no match. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` num_at

`*CONTAINS` (text_t s)

Results in Boolean TRUE value if the Text contains the string given in the argument. The input string cannot be bigger than 255 characters. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*CRC32`

Returns a 32-bit integer computed by applying a CRC (cyclic redundancy check) function to the selected text. This is the CRC function used by Ethernet, MPEG-2, PKZIP, GZIP, PNG, and many other applications. For example, the expression to compute the CRC value of the (first 1000 bytes of the) body of an HTTP request is: HTTP.REQ.BODY(1000).CRC32

`Returns:` num_at

`*DECODE_USING_TEXT_MODE`

Decodes the selected text using the currently configured text encoding methods like URLENCODED, BACKSLASH_ENCODED, PLUS_AS_SPACE, NOURLENCODED, NO_BACKSLASH_ENCODED and NO_PLUS_AS_SPACE. Text encoding methods are set using SET_TEXT_MODE method.

`Returns:` text_t

`*DECRYPT`

Decrypt the selected base64-encoded ciphertext using the configured encryptionParams.

`Returns:` text_t

`*DECRYPT` (binary_encoding_e in_encoding)

Decrypt the selected ciphertext using the configured encryptionParams.

`Parameters` (expressions not allowed) `:`

in_encoding- specifies how the input ciphertext is encoded. If the ciphertext is not encoded as specified, causes an Undef error.

`Returns:` text_t

`*DECRYPT` (text_t encryptionKey)

Decrypt the selected base64-encoded encrypted bytes using the configured encryption key.

`Parameters` (expressions not allowed) `:`

encryptionKey- identifies the encryptionKey object to provide the cipher method, mode, padding, key, encrypted format and optional initialization vector (IV).

`Returns:` text_t

`*DECRYPT` (text_t encryptionKey, binary_encoding_e in_encoding)

Decrypt the selected base64-encoded encrypted bytes using the configured encryption key.

`Parameters` (expressions not allowed) `:`

encryptionKey- identifies the encryptionKey object to provide the cipher method, mode, padding, key, encrypted format, and optional initialization vector (IV).

in_encoding- specifies how the input ciphertext is encoded. If the ciphertext is not encoded as specified, causes an Undef error.

`Returns:` text_t

`*DIGEST` (digest_method_e method)

Returns a byte sequence computed by applying the the specified message digest method to the selected text.

`Parameters` (expressions not allowed) `:`

method- digest method to apply to the input text

`Returns:` text_t

`*ENCRYPT`

Encrypt the selected plaintext bytes using the configured encryptionParams. The resulting ciphertext is base64-encoded.

`Returns:` text_t

`*ENCRYPT` (binary_encoding_e out_encoding)

Encrypt the selected plaintext bytes using the configured encryptionParams.

`Parameters` (expressions not allowed) `:`

out_encoding- specifies how the resulting ciphertext is encoded.

`Returns:` text_t

`*ENCRYPT` (text_t encryptionKey)

Encrypt the selected cleartext bytes using the configured encryption key.

`Parameters` (expressions not allowed) `:`

encryptionKey- identifies the encryptionKey object to provide the cipher method, mode, padding, key, encrypted format and optional initialization vector (IV).

`Returns:` text_t

`*ENCRYPT` (text_t encryptionKey, binary_encoding_e out_encoding)

Encrypt the selected cleartext bytes using the configured encryption key.

`Parameters` (expressions not allowed) `:`

encryptionKey- identifies the encryptionKey object to provide the cipher method, mode, padding, key, encrypted format and optional initialization vector (IV).

out_encoding- specifies how the resulting ciphertext is encoded.

`Returns:` text_t

`*ENDSWITH_ANY` (text_t patset_name)

Results in Boolean TRUE value if the Text ends with any of the strings that are bound to the patset or dataset named by the string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` bool_at

`*ENDSWITH_INDEX` (text_t patset_name)

Returns the numerical index of the matching string, if the Text ends with any of the strings that are bound to the patset or dataset named by the string argument. Returns 0 if there is no match. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` num_at

`*ENDSWITH` (text_t end)

Results in Boolean TRUE value if a suffix of the Text object matches the string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

end- String

`Returns:` bool_at

`*EQUALS_ANY` (text_t patset_name)

Results in Boolean TRUE value if the Text equals any of the strings that are bound to the patset or dataset named by the string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` bool_at

`*EQUALS_INDEX` (text_t patset_name)

Returns the numerical index of the matching string, if the Text equals any of the strings that are bound to the patset or dataset named by the string argument. Returns 0 if there is no match. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` num_at

`*GET_SIGNED16` (`uint` n, endian_e endianness)

Get the 16-bit signed binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

endianness- Select little or big endian

`Returns:` num_at

`*GET_SIGNED32` (`uint` n, endian_e endianness)

Get the 32-bit signed binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

endianness- Select little or big endian

`Returns:` num_at

`*GET_SIGNED8` (`uint` n)

Get the 8-bit signed binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

`Returns:` num_at

`*GET_UNSIGNED16` (`uint` n, endian_e endianness)

Get the 16-bit unsigned binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

endianness- Select little or big endian

`Returns:` num_at

`*GET_UNSIGNED32` (`uint` n, endian_e endianness)

Get the 32-bit unsigned binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

endianness- Select little or big endian

`Returns:` unsigned_long_at

`*GET_UNSIGNED64` (`uint` n, endian_e endianness)

Get the 64-bit unsigned binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

endianness- Select little or big endian

`Returns:` unsigned_long_at

`*GET_UNSIGNED8` (`uint` n)

Get the 8-bit unsigned binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

`Returns:` num_at

`*GET_URLSET_METADATA` (text_t urlset_name)

Returns metadata value corresponding to pattern in the urlset. The matching is case-insensitive for domains, but case-sensitive for paths. If no pattern is matched within the urlset, the return value is a NULL string. For example:

- HTTP.REQ.HOST.APPEND(HTTP.REQ.URL).GET_URLSET_METADATA("urlset_forbidden") returns value when the combined domain and URL is looked up in the urlset whose name is "urlset_forbidden".

`Parameters` (expressions not allowed) `:`

urlset_name- urlset name

`Returns:` text_t

`*GE` (text_t s)

Results in Boolean TRUE value if the Text object is greater than or equal to the input argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*GRPC`

Interprets a text_t string as a Protocol Buffer (protocol_buffer_t type). Example: HTTP.REQ.BODY(1000).GRPC.STRING(1).EQ("bookname")

`Returns:` protocol_buffer_t

`*GT` (text_t s)

Results in Boolean TRUE value if the Text object is greater than the input argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*HASH`

Returns a positive 31 bit integer value computed by applying a proprietary NetScaler hash function to the selected text. This function is not case- sensitive and ignores whitespaces. For example, applying the HASH function to two strings "Ab c" and "abc" would produce the same value. This

function should not be used for security purposes; use instead the DIGEST function with one of the standard digest methods.

`Returns:` num_at

`*HMAC` (text_t hmacKey)

Returns a byte sequence computed by applying the HMAC (Hash Message Authenticastion Code) function to the selected text using the configured HMAC key.

`Parameters` (expressions not allowed) `:`

hmacKey- indentifies the hmacKey object to provide the digest (hash) method and the key.

`Returns:` text_t

`*HMAC` (text_t hmacKey, binary_encoding_e out_encoding)

Returns a byte sequence computed by applying the HMAC (Hash Message Authenticastion Code) function to the selected text using the configured HMAC key .

`Parameters` (expressions not allowed) `:`

hmacKey- indentifies the hmacKey object to provide the digest (hash) method and the key.

out_encoding- specifies how the resulting HMAC is encoded.

`Returns:` text_t

`*HTML_XML_SAFE`

Apply XML safe transform and select text.

Converts '<', '>' and '&' in the input text to '<', '>' and '&' respectively; other characters in the input are not modified. This transform safeguards against XSS based attacks. This is a read only operation.

`Returns:` text_t

`*HTTP_HEADER_SAFE`

Apply Header safe transform and select text. Converts all new line ('\\n') characters present in the input text to '%0A' so that they can safely be used in HTTP headers. This transform safeguards against response-splitting attacks. This is a read only operation.

`Returns:` text_t

`*HTTP_URL_SAFE`

Apply URL safe transform and select text. Converts URL unsafe characters to corresponding '%xx' values and retains the rest. This is a read only operation.

```
Based on RFC2396, following are considered URL safe characters:

    Alpha-numeric characters: a-z, A-Z, 0-9

    Hyphen and underscore: "-", "_"

    Dot: "."

    Exclamation mark: "!"

    Tilde: "~"

    Asterix: "&ast;"

    Single quote: "'"

    Open and close parentheses: "(", ")"

    Semi-colon: ";"

    Colon: ":"

    At symbol: "@"

    Question mark: "?"

    Equals: "="

    Dollar: "$"

    Percent: "%"

    Ampersand: "&"

    Plus: "+"
```

```
    Comma: ","

    Forward slash: ".html"
```

The rest are converted to %XX encoding, 'XX' is the hex-based representation of the input character. If the requirement is to encode all but URL unreserved characters, please consider using URL_RESERVED_CHARS_SAFE method.

`Returns:` text_t

`*IS_BOOL_AT`

Results in Boolean TRUE value if the Text is of boolean type.

`Returns:` bool_at

`*IS_DOUBLE_AT`

Results in Boolean TRUE value if the Text is of double data type.

`Returns:` bool_at

`*IS_IPV6_AT`

Results in Boolean TRUE value if the Text is of IPv6 data type.

`Returns:` bool_at

`*IS_IPV6_SUBNET_AT`

Results in Boolean TRUE value if the Text is of IPv6 subnet data type.

`Returns:` bool_at

`*IS_IP_AT`

Results in Boolean TRUE value if the Text is of IPv4 data type.

`Returns:` bool_at

`*IS_MAC_ADDRESS_AT`

Results in Boolean TRUE value if the Text is of mac address data type.

`Returns:` bool_at

`*IS_NUM_AT`

Results in Boolean TRUE value if the Text is of number type.

`Returns:` bool_at

`*IS_NUM_AT` (num_format_e format)

Results in Boolean TRUE value if the Text is of number type with given input base.

`Parameters` (expressions not allowed) `:`

format- number format

`Returns:` bool_at

`*IS_STRINGMAP_KEY` (text_t string_map_name)

Returns true if the string that it operates on is present in the string map. Text mode IGNORECASE, NOIGNORECASE - controls whether key lookup in string map is case sensitive or not. For example:

- HTTP.REQ.URL.IS_STRINGMAP_KEY("url_stringmap") returns true if value of HTTP.REQ.URL is present as key in the string map whose name is "url_stringmap".
- HTTP.REQ.URL.SET_TEXT_MODE(IGNORECASE). IS_STRINGMAP_KEY("url_stringmap") returns true if value of HTTP.REQ.URL is present as key in the string map whose name is "url_stringmap". Key lookup in this case is done case-insensitively.

`Parameters` (expressions not allowed) `:`

string_map_name- identifies the string map.

`Returns:` bool_at

`*IS_TIME_AT`

Results in Boolean TRUE if the Text follows any of the standard time formats given below, otherwise false. Tue, 05 Nov 1994 08:12:31 GMT RFC822 Tuesday, 05-Nov-94 08:12:31 GMT RFC850 Tue Nov 4 08:12:31 1994 asctime

`Returns:` bool_at

`*IS_UNSIGNED_LONG_AT`

Results in Boolean TRUE value if the Text is of unsigned long data type.

`Returns:` bool_at

`*IS_UNSIGNED_LONG_AT` (num_format_e format)

Results in Boolean TRUE value if the Text is of unsigned long data type with given input base.

`Parameters` (expressions not allowed) `:`

format- number format

`Returns:` bool_at

`*JWT_VERIFY_CERTKEY` (text_t certkey_name)

Verifies the signature on the input JSON Web Token (JWT), using the RSA public key in the X.509 certificate in the specified certkey object. The token has the format HEADER.PAYLOAD.SIGNATURE where

- HEADER is a base64-encoded JSON structure indicating a signature algorithm and token type, e.g.'{"alg":"RS256","typ":"JWT"}'
- PAYLOAD is a base64-encoded JSON structure with asserted claims, e.g. '{"loggedInAs":"admin","iat":1422779638}'
- SIGNATURE is the base64-encoded bytes for the signature on HEADER.PAYLOAD.

Returns true if the signature is verified for the header and payload using the specified public key; false if the signature is not verified

`Parameters``:`

certkey_name- identifies the certkey object containing an X.509 certificate holding the RSA public key. Results in an Undef error if the certkey object does not exist or does not contain an X.509 certificate with an RSA public key, if the token is not correctly formatted, or if the verification operation cannot complete.

`Returns:` bool_at

`*JWT_VERIFY_XML` (text_t xml_pkey)

Verifies the signature on the input JSON Web Token (JWT), using the RSA public key supplied by the specified XML element. The token has the format HEADER.PAYLOAD.SIGNATURE where

- HEADER is a base64-encoded JSON structure indicating a signature algorithm and token type, e.g.'{"alg":"RS256","typ":"JWT"}'

- PAYLOAD is a base64-encoded JSON structure with asserted claims, e.g. '{"loggedInAs":"admin","iat":1422779638}'
- SIGNATURE is the base64-encoded bytes for the signature on HEADER.PAYLOAD.

Returns true if the signature is verified for the header and payload using the specified public key; false if the signature is not verified

`Parameters``:`

xml_pkey- an expression that supplies an <RSAKeyValue> element with the public key. Results in an Undef error if the XML element is invalid or does not correctly specify an RSA public key, if the token is not correctly formatted, or if the verification operation cannot complete.

`Returns:` bool_at

`*LENGTH`

Results in a Number Value that is the number of characters (not bytes) in the Text object.

`Returns:` num_at

`*LE` (text_t s)

Results in Boolean TRUE value if the Text object is less than or equal to the input argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*LOCATION_LONG`

Get the location qualifier from CLIENT.IP.SRC.LOCATION.GET(n) (ISO short name) and then convert it to human readable long name. This conversion is valid only for country names. Correct Country qualifier value (number) in GET(n) is left up to the user as qualifiers are user configurable. Expression example: CLIENT.IP.SRC.LOCATION.GET(1).LOCATION_LONG For example: Data from each expression CLIENT.IP.SRC.LOCATION: NA.US.California.SantaClara.*.* CLIENT.IP.SRC.LOCATION.GET(1): US CLIENT.IP.SRC.LOCATION.GET(1).LOCATION_LONG: United States

`Returns:` text_t

`*LT` (text_t s)

Results in Boolean TRUE value if the Text object is less than the input argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*MAP_STRING_DEFAULT_TO_KEY` (text_t string_map_name)

Returns the value corresponding to the key in the string map. This is similar to the MAP_STRING method, but if the key is not present then instead of returning a null string, it returns the key itself. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

string_map_name- identifies the string map.

`Returns:` text_t

`*MAP_STRING` (text_t string_map_name)

Returns value corresponding to key in the string map. Key is the string that it is given as input. Text mode IGNORECASE, NOIGNORECASE - controls whether key lookup in string map is case sensitive or not. For example:

- HTTP.REQ.URL.MAP_STRING("url_stringmap") returns value when the value of HTTP.REQ.URL is used as key in the string map whose name is "url_stringmap".
- HTTP.REQ.URL.SET_TEXT_MODE(IGNORECASE). MAP_STRING("url_stringmap") returns value when the value of HTTP.REQ.URL is used as key in the string map whose name is "url_stringmap". Key lookup in this case is done case-insensitively.

`Parameters` (expressions not allowed) `:`

string_map_name- identifies the string map.

`Returns:` text_t

`*MARK_SAFE`

Mark the PIXL expression safe without applying any safe transform.

`Returns:` text_t

`*MAX` (text_t s)

Compares the string argument with the current string and returns the max string. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*MIN` (text_t s)

Compares the string argument with the current string and returns the min string. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*NE` (text_t s)

Results in Boolean TRUE value if the Text object is not equal to the input argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*NORMALIZE_URL`

Normalize URL. Normalizes a URL by doing "percent" decoding. See the description for URLENCODED in the SET_TEXT_MODE function. This performs the equivalent of SET_TEXT_MODE(URLENCODED).DECODE_USING_TEXT_MODE, except that it does not change the value of the current text mode.

`Returns:` text_t

`*PKEY_ENCRYPT_PEM_NO_PADDING` (text_t pem_pkey)

Encrypts the input text using the RSA public key provided by the PEM string and RSA_NO_PADDING padding method. The input text to be encrypted cannot be longer than the public key length minus 11 bytes for padding. For example, for a 1024-bit (128 byte) key, the input text cannot be longer than 128 - 11 = 117 bytes. An Undef error will occur if the input text is too long. A null input will also cause an Undef error. Returns the (unencoded binary) encrypted text, which is typically base-64 encoded for use in a message.

`Parameters``:`

pem_pkey- a text expression that supplies a RSA public key in the PEM format. If the text value is not a valid PEM RSA PUBLIC KEY encoding, an Undef error will occur. Example (a 1024-bit public key):

```
"-----BEGIN RSA PUBLIC KEY-----" +

"MIGJAoGBAKl5vgQEj73Kxp+9yn1v5gPR1pnc4oLM2a0kaWwBOsB6rzCIy6znwnvw" +

"CY1xRvQhRlJSAyJbloL7wZFIJ2FOR8Cz+8ZQWXU2syG+udi4EnWqLgFYowF9zK+o" +

"79az597eNPAjsHZ/C2oL/+6qY5a/f1z8bQPrHC4GpFfAEJhh/+NnAgMBAAE=" +

"-----END RSA PUBLIC KEY-----"
```

`Returns:` text_t

`*PKEY_ENCRYPT_PEM` (text_t pem_pkey)

Encrypts the input text using the RSA public key provided by the PEM string and the RSA_PKCS1_PADDING padding method. The input text to be encrypted cannot be longer than the public key length minus 11 bytes for padding. For example, for a 1024-bit (128 byte) key, the input text cannot be longer than 128 - 11 = 117 bytes. An Undef error will occur if the input text is too long. A null input will also cause an Undef error. Returns the (unencoded binary) encrypted text, which is typically base-64 encoded for use in a message.

`Parameters``:`

pem_pkey- a text expression that supplies a RSA public key in the PEM format. If the text value is not a valid PEM RSA PUBLIC KEY encoding, an Undef error will occur. Example (a 1024-bit public key):

```
"-----BEGIN RSA PUBLIC KEY-----" +

"MIGJAoGBAKl5vgQEj73Kxp+9yn1v5gPR1pnc4oLM2a0kaWwBOsB6rzCIy6znwnvw" +

"CY1xRvQhRlJSAyJbloL7wZFIJ2FOR8Cz+8ZQWXU2syG+udi4EnWqLgFYowF9zK+o" +

"79az597eNPAjsHZ/C2oL/+6qY5a/f1z8bQPrHC4GpFfAEJhh/+NnAgMBAAE=" +

"-----END RSA PUBLIC KEY-----"
```

`Returns:` text_t

`*PKEY_SIGN_CERTKEY` (text_t certkey_name)

Generates a binary digital signature using the SHA-256 message digest function and an RSA private key from the specified SSL certKey object.

`Parameters``:`

certkey_name- identifies the configured certKey object. Results in an Undef error if the certkey object does not exist or does not contain an RSA private key, or if the signing operation cannot complete.

`Returns:` text_t

`*PKEY_SIGN_XML` (text_t xml_pkey)

Generates a binary digital signature using the SHA-256 message digest function and an RSA private key from the specified XML element.

`Parameters``:`

xml_pkey- an expression that supplies an <RSAKeyValue> element with the private key. Example: <RSAKeyValue> <Modulus>qXm+BASPvcrGn73KfW/
mA9HWmdzigszZrSRpbAE6wHqvMIjLrOfCe/
AJjXFG9CFGUlIDIluWgvvBkUgnYU5HwLP7xlBZdTazIb652LgSdaouAVijAX3Mr6jv1rPn3t408COwdn8Lagv/
7qpjlr9/XPxtA+scLgakV8AQmGH/42c=</Modulus> <Exponent>AQAB</Exponent>"zNjysxcIJV/
J9cTpIgPp2/x1IXHT5GTH8OMuNad0qtRSLjU1QYUmmkm9QcJJAN+7h8FEXWGabySUzBrHj/
IEbw==" <DP>QavUDQLLQpnPJXtVAo6CYhxOMCd68mwTxYKKNLjmC0pd54SFHllTLPE1FZU5EjK6q3nCeijonpfH+XX
DP> <DQ>EiXOKouJzzXTQJC3TqomF7Uf81yQNxWumOqnd11kepXgyfMwyqMvLlAGEkNSEF/
Bz18R3Wv+MIZ/IC3nLBt2xQ==</DQ>

<InverseQ>ocuCmz36CP+N2aGqxaU+BKD5+3RLgRq9LFhULEz2jKx0iV9r76jsAxn3sLcTYYO9eqRPy2cz74AU
nw==</InverseQ> <D>fTBD773a3GzcmgVdfZlaBLpN1ux2mf5uUVrTUQf7eVFm9egm4/
tzC5A9zjC+I/oscwTH8epL3UfRLdtp05Q6pWfJBXEnGo0QmOFFBK4pLx/
5JJpPGZ69ovDFEVOUHyiCfKE/g97T4WX3us0nFe1272zwGlHarM1YYwvfeE08UdE=</D> </
RSAKeyValue> Results in an Undef error if the XML element is invalid or does not correctly specify an RSA private key, or if the signing operation cannot complete.

`Returns:` text_t

`*PKEY_VERIFY_CERTKEY` (text_t certkey_name, text_t signature)

Verifies if the input text matches the specified signature generated using the SHA-256 messge digest function and the RSA private key associated with the specified RSA public key in the X.509 certificate in the specified certKey object. Returns true if the signature is verified, false otherwise.

`Parameters``:`

certkey_name- identifies the certkey object containing an X.509 certificate holding the RSA public key.

signature- the binary signature. Results in an Undef error if the certkey object does not exist or does not contain an X.509 certificate with an RSA public key, or if the verification operation cannot complete.

`Returns:` bool_at

`*PKEY_VERIFY_XML` (text_t xml_pkey, text_t signature)

Verifies if the input text matches the specified signature generated using the SHA-256 messge digest function and the RSA private key associated with the RSA public key supplied by the specified XML element. Returns true if the signature is verified, false otherwise.

`Parameters``:`

xml_pkey- an expression that supplies an <RSAKeyVAlue> element with the public key. Example: <RSAKeyValue> <Modulus>qXm+BASPvcrGn73KfW/
mA9HWmdzigszZrSRpbAE6wHqvMIjLrOfCe/
AJjXFG9CFGUlIDIluWgvvBkUgnYU5HwLP7xlBZdTazIb652LgSdaouAVijAX3Mr6jv1rPn3t408COwdn8Lagv/
7qpjlr9/XPxtA+scLgakV8AQmGH/42c=</Modulus> <Exponent>AQAB</Exponent> </
RSAKeyValue>

signature- the binary signature. Results in an Undef error if the XML element is invalid or does not correctly specify an RSA public key, or if the verification operation cannot complete.

`Returns:` bool_at

`*PREFIX` (`char` c, `uint` i)

Select a prefix of the Text. The selected prefix is the longest prefix that has at most Count (2nd argument) occurrences of character in the 1st argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

c- Character

i- Count

`Returns:` text_t

`*PREFIX` (`uint` i)

Select a prefix of the Text. The length of the prefix is equal to the number in the argument. If there aren't enough characters in the Text object then the entire Text is selected.

`Parameters``:`

i- Prefix Length

`Returns:` text_t

`*REGEX_MATCH` (`re` regex)

Returns TRUE if and only if the text contains at least one match of the regular expression argument. The match may occur anywhere within the text - if you wish to "anchor" this, use "\^" at the start of the regex and/or "$" at the end of the regex.

The regular expression has to be of the format: `re<delimiter>regular expression<same delimiter>`

The regular expression cannot be bigger than 1499 characters.

The regular expression should be acceptable by the PCRE regular expression library. Look at http://www.pcre.org/pcre.txt for documentation on the regular expression syntax. In particular, look at the pcrepattern man page.

There are some differences in the allowed syntax w.r.t PCRE syntax. Backreferences are not allowed. It is recommended not to use recursive regular expressions. The dot metacharacter matches newlines also. Unicode is not supported. SET_TEXT_MODE(IGNORECASE) overrides the (?i) internal option specified in the regular expression.

The PCRE library configuration can be seen in the system log, after executing 'nsapimgr -B" call ns_pixl_regex_show_config()"' at the shell prompt.

Some examples:

- HTTP.REQ.HOSTNAME.REGEX_MATCH(re/\[\[:alpha:\]\]+(abc){2,3}/)
- HTTP.REQ.URL.SET_TEXT_MODE(URLENCODED).REGEX_MATCH(re#(a*b+c*)#)
- HTTP.REQ.URL.REGEX_MATCH(re/a(?i)b/) matches ab and aB
- HTTP.REQ.URL.SET_TEXT_MODE(IGNORECASE).REGEX_MATCH(re/ab/) matches ab, aB, Ab and AB
- HTTP.REQ.BODY.REGEX_MATCH(re/(?ixm) (\^ab (.*) cd$) /) does a case-insensitive, multiline match where the dot metacharacter matches newline also. The regex itself can contain whitespace which will be ignored during the matching (x - extended regex).

This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

regex- Regular Expression

`Returns:` bool_at

`*REGEX_REPLACE` (`re` regex, text_t replacement, replacemode_e mode)

Selects the text that matches the given regular expression argument and replaces it with the the text given in the second argument. The third argument specifies whether the first match is only replaced when multiple matches occur in the text or all matches are replaced. The match may occur anywhere within the text - if you wish to "anchor" this, use "\^" at the start of the regex and/or "$" at the end of the regex. When the regular expression does not match the given string then the same string is returned.

For example: HTTP.RES.BODY(999).REGEX_REPLACE(re!\\bpassword:\\s*\\b!, "password: ***", ALL) will replace all occurrences of "password:" with "password: ***" This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

regex- Regular Expression

replacement- String to replace the match

mode- Mode of replacement

`Returns:` text_t

`*REGEX_SELECT` (`re` regex)

Selects the text that matches the given regular expression argument. The first match is returned when multiple matches occur in the text. The match may occur anywhere within the text - if you wish to "anchor" this, use "\^" at the start of the regex and/or "$" at the end of the regex. When the regular expression does not match the given string, a Text object of length of 0 is returned.

For example: HTTP.REQ.HEADER("via").REGEX_SELECT(re!NS-CACHE-\\d\\.\\d:\\s*\\d{1,3}!) will select "NS-CACHE-7.0: 70" This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

regex- Regular Expression

`Returns:` text_t

`*REPEAT` (`uint` i)

Produces a string which contains 'i' sequential copies of the input string.

`Parameters``:`

i- the number of times to repeat the string (0 or more)

`Returns:` text_t

`*SET_CHAR_SET` (charset_e charset)

Set the character set to use for subsequent functions that use text.

`Parameters` (expressions not allowed) `:`

charset- Character Set

`Returns:` http_hostname_t

`*SET_TEXT_MODE` (textmode_e mode)

The mode setting of a Text object controls the behavior of many Text operations. The Text mode settings may also control the behavior of some operations in objects (like List) that build upon the Text object. IGNORECASE, NOIGNORECASE - controls whether string comparison is case sensitive or not. URLENCODED - If set then all Text operations are carried out after translating all %HH or %uHHHH encodings in the underlying byte stream. 1. %HH will be translated to the character Y where HH denotes the ascii value of character Y in hexadecimal. For example, the encoded text "http%3a/.html" will be decoded to "http:/.html" 2. %uWWHH will be translated to the character sequence YZ where WW denotes the ascii value of character Y in hexadecimal and HH denotes the ascii value of character Z in hexadecimal. For example, the encoded text "http%u3a2f.html" and "http%u003a/.html" will both be decoded to"http:/.html" NOURLENCODED - Indicates that no percent encodings are present in the Text object. No percent decoding will be performed on the Text object. PLUS_AS_SPACE - If set then all Text operations are carried out after converting occurrences of the plus character to whitespace. For example, the text "hello+world" will be decoded to "hello world" NO_PLUS_AS_SPACE - If set, then the plus character will not be converted to whitespace in the Text object. BACKSLASH_ENCODED - If set, then all Text operations are carried out after performing the following operations: 1. \\XXX will be translated to the character Y where XXX denotes the ascii value of character Y in octal. The valid range of octal values for this type of encoding is \\0 to \\377. For example, the encoded text "http\\72/.html" and "http\\072/.html" will both be decoded to "http:/.html" 2. \\xHH will be translated to the character Y where HH denotes the ascii value of character Y in hexadecimal. For example, the encoded text "http\\x3a/.html" will be decoded to "http:/.html" 3. \\\\uWWXX will be translated to the character sequence YZ where WW denotes the ascii value of character Y in hexadecimal and XX denotes the ascii value of character Z in hexadecimal. For example, the encoded text "http%u3a2f.html" and "http%u003a/.html" will both be decoded to"http:/.html" 4. Occurences of "\\b", "\\n", "\\t", "\\f" and "\\r" are translated to the corresponding ascii characters. NO_BACKSLASH_ENCODED - If set, then backslash decoding will not be performed on the Text object. BAD_ENCODE_RAISE_UNDEF - If set, then UNDEF is raised if either the URLENCODED or BACKSLASH_ENCODED mode is set and a bad encoding corresponding to the specified encoding mode is encountered. NO_BAD_ENCODE_RAISE_UNDEF - If set, then UNDEF will not be raised when a bad encoding is encountered in the Text object. The Text operations operate on characters (as opposed to operating on bytes). By default a single byte represents a character using the ASCII encoding. But if URLENCODED mode is set then 3 bytes may represent a character. A PREFIX(3) operation will select the first 3 characters in the Text object. That means it may select up to 9 bytes for URLENCODED Text object. In the case of multibyte decodings as a result of %uXXXX or \\\\uXXXX, Text operations which attempt to treat the multiple decoded bytes as distinct characters are not allowed.

`Parameters` (expressions not allowed) `:`

mode- Text Mode

`Returns:` http_hostname_t

`*SKIP` (`char` c, `uint` i)

Select the Text after skipping over a prefix of the current Text. The skipped over prefix is the longest prefix that has at most Count (2nd argument) occurrences of character in the 1st argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

c- Character

i- Count

`Returns:` text_t

`*SKIP` (`uint` i)

Select the Text after skipping over a prefix in the current Text. The length of the prefix is equal to the number in the argument. If there aren't enough characters in the Text object then the entire Text is skipped over.

`Parameters` (expressions not allowed) `:`

i- Prefix Length

`Returns:` text_t

`*STARTSWITH_ANY` (text_t patset_name)

Results in Boolean TRUE value if the Text starts with any of the strings that are bound to the patset or dataset named by the string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` bool_at

`*STARTSWITH_INDEX` (text_t patset_name)

Returns the numerical index of the matching string, if the Text starts with any of the strings that are bound to the patset or dataset named by the string argument. Returns 0 if there is no match. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` num_at

`*STARTSWITH` (text_t start)

Results in Boolean TRUE value if a prefix of the Text object matches the string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

start- String

`Returns:` bool_at

`*STRIP_CHARS` (text_t s)

From the selected text remove the characters specified in the string.

For example: Say the selected text is / "foo.xyz=bar" /. Then on executing STRIP_CHARS('.=') or STRIP_CHARS('..=') the selected text will become /fooxyzbar /. Note that repeating character has same effect as it would be if it present only once. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*STRIP_END_CHARS` (text_t s)

Selects the Text after stripping off characters in the end of the current Text object.

For example: Say the selected text is / "foo.xyz=bar" /. Then on executing STRIP_END_CHARS('ar') the selected text will become /foo.xyz=b /. Note that repeating character has same effect as it would be if it present only once. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*STRIP_END_WS`

Selects the Text after stripping off white space in the end of the current Text object.

`Returns:` text_t

`*STRIP_START_CHARS` (text_t s)

Selects the Text after stripping off characters in the beginning of the current Text object.

For example: Say the selected text is / "foo.xyz=bar" /. Then on executing STRIP_START_CHARS('of') the selected text will become /.xyz=bar /. Note that repeating character has same effect as it would be if it present only once. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*STRIP_START_WS`

Selects the Text after stripping off white space in the beginning of the current Text object.

`Returns:` text_t

`*SUBSTR_ANY` (text_t patset_name)

Select any one sub-string that matches any string in the given patset or dataset. The patset cannot have strings longer than 255 characters. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` text_t

`*SUBSTR` (`uint` start, `uint` len)

Select the Text object of the given length at the given offset. Offset it 0 based. If there aren't enough characters after the offset then all the remaining characters are selected.

`Parameters``:`

start- Offset

len- Length

`Returns:` text_t

`*SUBSTR` (text_t s)

Select the first Text object that matches the input string argument. The input string cannot be bigger than 255 characters. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*SUFFIX` (`char` c, `uint` i)

Select a suffix of the Text. The selected suffix is the longest possible suffix containing at most Count (2nd arg) occurrences of the character in the 1st argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

c- Character

i- Count

`Returns:` text_t

`*SUFFIX` (`uint` i)

Select a suffix of the Text. The length of the suffix is equal to the number in the argument. If there aren't enough characters in the Text object then the entire Text is selected.

`Parameters``:`

i- Suffix Length

`Returns:` text_t

`*TO_LOWER`

Converts the selected text to lower case.

For example, the string "ABCd" is converted to "abcd"

`Returns:` text_t

`*TO_UPPER`

Converts the selected text to upper case.

For example, the string "abcD" is converted to "ABCD"

`Returns:` text_t

`*TRUNCATE` (`char` c, `uint` i)

Select the Text after truncating a suffix from the current Text object. The truncated suffix is the longest possible suffix containing at most Count (2nd arg) occurrences of the character in the 1st argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

c- Character

i- Count

`Returns:` text_t

`*TRUNCATE` (`uint` i)

Select the Text after truncating a suffix of the Text. The length of the suffix truncated is equal to the number in the argument. If there aren't enough characters in the Text then then all the characters are truncated.

`Parameters``:`

i- Suffix Length

`Returns:` text_t

`*TYPECAST_AVP_T`

Convert text_t to avp_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (avp_t : Operations that can be performed on the returned AVPs.

`Note:` An AVP can have multiple instances in a Diameter message. However, the system can access only the first 16 instances.

`Example:`

- To get the first value of AVP code 266 from a request, use: DIAMETER.REQ.AVP(266).VALUE(0).
- To get the fourth value of AVP code 266 from a request, use: DIAMETER.REQ.AVP(266).VALUE(3).
- To check if AVP code 1000 in the response has the vendor-specific bit set, use: DIAMETER.RES.AVP(1000).IS_VENDOR_SPECIFIC.

)

`Returns:` avp_t

`*TYPECAST_AVP_UNUM_T`

Convert text_t to avp_unum_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (avp_unum_t : In Diameter AVP based expressions can be written as DIAMETER.REQ.AVP(<avpcode>). For example Auth-Application-Id AVP (AVP code 258) can be extracted as DIAMETER.REQ.AVP(258) For few of the important AVPs we provide aliases. For example this AVP based expression can also be written as DIAMETER.REQ.AUTH_APPLICATION_ID. This expression returns either a object of class avp_t or returns a numerical value (object of class unsigned_long_at). The numerical value for this object is derived from the value in first instance of the AVP.)

`Returns:` avp_unum_t

`*TYPECAST_BOOL_AT`

Convert text_t to bool_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (bool_at : Boolean Operations)

`Returns:` bool_at

`*TYPECAST_COOKIE_T`

Convert text_t to cookie_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (cookie_t : The HTTP Cookie type provides operations for a cookie as it appears in the Set-Cookie and Set-Cookie2 header. In this type the Name-Value List operations are also available. The first delimiter is = and the element delimiter is ;. Multiple consecutive ; are treated as one. (Same as applying the method IGNORE_EMPTY_ELEMENTS on a Name-Value List.) You can use the Name-value List operations to access cookie attributes. The name comparison for all list operations is case insensitive. In this type Text operations are also available. Each cookie begins with a COOKIE_NAME=COOKIE_VALUE pair followed by zero or more semi-colon separated attribute-value pairs. If an attribute appears more than once in a cookie, the value associated with the first appearance of the attribute is returned.

Format Cookie: Cookie1=Value;Version=decimal;Value;Domain=Value;Path=Value)

`Returns:` cookie_t

`*TYPECAST_DIAMETER_FLAG_T`

Convert text_t to diameter_flag_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (diameter_flag_t : Provides operation to treat the underlying 1 byte as set of bit flags. then set/unset/test/reset_all operations can be done on flag)

`Returns:` diameter_flag_t

`*TYPECAST_DNS_DOMAINNAME_T`

Convert text_t to dns_domainname_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (dns_domainname_t : This object provides operations for parsing the DNS domain name as it appears at various places in the DNS data. The format is abc.foo.com.)

`Returns:` dns_domainname_t

`*TYPECAST_DNS_FLAG_T`

Convert text_t to dns_flag_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (dns_flag_t : Provides operations to test/set/unset a flag in dns header.)

`Returns:` dns_flag_t

`*TYPECAST_DOUBLE_AT`

Convert text_t to double_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_at : Double Value)

`Returns:` double_at

`*TYPECAST_DOUBLE_T` (double_format_e format)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error.)

`Parameters` (expressions not allowed) `:`

format- Format

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, double_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, ip_address_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given

format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, num_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, time_local_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, time_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, unsigned_long_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_HTTP_CACHE_CONTROL_T`

Convert text_t to http_cache_control_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_cache_control_t : This object provides for the ability to work on HTTP Cache-Control headers. The name comparison for all list operations is case insensitive.)

`Returns:` http_cache_control_t

`*TYPECAST_HTTP_CONTENT_LENGTH_T`

Convert text_t to http_content_length_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_content_length_t : The HTTP.REQ.CONTENT_LENGTH or HTTP.RES.CONTENT_LENGTH object can be treated as a HTTP Header or as a Number. The numerical value for this object is derived from the value in the last instance of the Content-Length header.)

`Returns:` http_content_length_t

`*TYPECAST_HTTP_COOKIE_T`

Convert text_t to http_cookie_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_cookie_t : This object provides operations for parsing the HTTP cookie header. The name-value pair is derived from the value in the last instance of Cookie header. The format is Cookie : name0=value0; name1=value1; An HTTP Cookie header can have multiple occurrences. COUNT will return a Number containing how many headers of the current type exist. The name comparison for all list operations is case insensitive. The system does not keep track of more than 15 HTTP headers. The result will be undefined if there are more than 15 instances of the header.)

`Returns:` http_cookie_t

`*TYPECAST_HTTP_DATE_T`

Convert text_t to http_date_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_date_t : The HTTP.REQ.DATE or HTTP.RES.DATE object can be treated as a HTTP header or a Time object. The Time value is derived from the value in the last instance of the Date header. The date formats supported are RFC 822 (updated by RFC 1123), RFC 1036 (obsoletes RFC850) and ANSI C asctime() formats.)

`Returns:` http_date_t

`*TYPECAST_HTTP_HEADER_T` (text_t name)

Convert text_t to http_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_header_t : When typecasting a Text object to HTTP Header a header name must be provided.For example: HTTP.REQ.HEADER("MyHdr").TYPECAST_HTTP_HEADER_T("InHdr"))

`Parameters` (expressions not allowed) `:`

name- Header Name

`Returns:` http_header_t

`*TYPECAST_HTTP_HOSTNAME_T`

Convert text_t to http_hostname_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_hostname_t : This object provides operations for parsing the HTTP hostname as it appears at various places in the HTTP protocol data. The format is abc.foo.com:8080.)

`Returns:` http_hostname_t

`*TYPECAST_HTTP_METHOD_T`

Convert text_t to http_method_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_method_t : This object provides Text operations and HTTP Request Method Enum operations on the HTTP request method.)

`Returns:` http_method_t

`*TYPECAST_HTTP_SET_COOKIE_T`

Convert text_t to http_set_cookie_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_set_cookie_t : HTTP.RES.SET_COOKIE provides operations for parsing and operating on the SET-COOKIE header that is present in the HTTP response. HTTP Set-Cookie header supports Text and HTTP Header operations. For most Text operations the value in the last Set-Cookie header is selected. HTTP Set-Cookie header also supports special operations to extract cookies from the response. It is assumed that there will be only one cookie in a Set-Cookie header.)

`Returns:` http_set_cookie_t

`*TYPECAST_HTTP_URL_T`

Convert text_t to http_url_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_url_t : HTTP.REQ.URL provides operations for parsing and operating on the URL that is present in the first line of the HTTP request header. The supported format is \[<protocol>://<hostname>\]<path>?<query>. The Text object backing a HTTP URL object has the Text Mode set to URLENCODED by default.)

`Returns:` http_url_t

`*TYPECAST_HTTP_VERSION_T`

Convert text_t to http_version_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_version_t : HTTP.REQ.VERSION or HTTP.RES.VERSION provide operations to extract HTTP version information.)

`Returns:` http_version_t

`*TYPECAST_IPV6_ADDRESS_AT`

Convert text_t to ipv6_address_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ipv6_address_at : Provides operations for the 128-bit IPv6 address value. Some general information regarding IPv6 expressions: IPv6 PIXL expressions can be combined with other PIXL expressions using the '+' operator. The output is expected to be the concatenation of the string representations of the individual PIXL expressions. No other operator other than '+' is expected to work when any of the operands is an IPv6 PIXL expression. Also, IPv6 PIXL expressions can be combined with any other type of PIXL expression except a PIXL expression that produces a bool result. In other words, if A and/or B are two IPv6 addresses, A+B should result in the string AB. When one of A or B is an IPv6 address, the other can only be a number or a string and not a boolean. Further, when A and/or B is an IPv6 address, the only operator allowed between them is '+'.

Example: Let the client source IPv6 address be ABCD:1234::ABCD. Let the server destination IPv4 address be 10.100.10.100. Then the expression CLIENT.IPV6.SRC + SERVER.IP.DST should produce the output "ABCD:1234::ABCD10.100.10.100". Similarly, CLIENT.IPV6.SRC + 5 should produce the result ABCD:1234::ABCD5)

`Returns:` ipv6_address_at

`*TYPECAST_IPV6_ADDRESS_T`

Convert text_t to ipv6_address_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ipv6_address_t : This object represents an IPv6 address present in the 1000:1001:CD10:0000:0000:89AB:4567:CDEF format.)

`Returns:` ipv6_address_t

`*TYPECAST_IPV6_SUBNET_AT`

Convert text_t to ipv6_subnet_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ipv6_subnet_at : Provides operations for the integral IPv6 subnet address value.)

`Returns:` ipv6_subnet_at

`*TYPECAST_IPV6_SUBNET_T`

Convert text_t to ipv6_subnet_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ipv6_subnet_t : This object represents an IPv6 subnet address present in the 1000:1001:CD10:0000:0000:89AB:4567:CDEF/64 format.)

`Returns:` ipv6_subnet_t

`*TYPECAST_IP_ADDRESS_AT`

Convert text_t to ip_address_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ip_address_at : Provides operations for the 32-bit integral IP address value.)

`Returns:` ip_address_at

`*TYPECAST_IP_ADDRESS_T`

Convert text_t to ip_address_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ip_address_t : Represents an IP address present in the 10.100.200.1 format.)

`Returns:` ip_address_t

`*TYPECAST_IP_OPTIONS_T`

Convert text_t to ip_options_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ip_options_t : IP protocol options)

`Returns:` ip_options_t

`*TYPECAST_IP_OPTIONS_TYPE_T`

Convert text_t to ip_options_type_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ip_options_type_t : IP Options Type)

`Returns:` ip_options_type_t

`*TYPECAST_IP_TOS_T`

Convert text_t to ip_tos_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ip_tos_t : Provides operations to TOS field in IP header.)

`Returns:` ip_tos_t

`*TYPECAST_LIST_T` (`char` sep)

Convert text_t to list_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (list_t : The character separator has to be provided when typecasting a textual context to list type. The current text mode has no effect on the character separator. For example if the current text mode is IGNORECASE and the separator is p then P will not be treated as a separator.)

`Parameters` (expressions not allowed) `:`

sep- Separator

`Returns:` list_t

`*TYPECAST_MAC_ADDRESS_AT`

Convert text_t to mac_address_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (mac_address_at : Provides operations for the 48-bit MAC address value.)

`Returns:` mac_address_at

`*TYPECAST_MAC_ADDRESS_T`

Convert text_t to mac_address_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (mac_address_t : Represents a MAC address present in the 12:34:56:78:9a:bc format.)

`Returns:` mac_address_t

`*TYPECAST_NUM_AT`

Convert text_t to num_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (num_at : Number Value)

`Returns:` num_at

`*TYPECAST_NUM_T` (num_format_e format)

Convert text_t to num_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (num_t : Treat the underlying text as a Number in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error.)

`Parameters` (expressions not allowed) `:`

format- Format

`Returns:` num_t

`*TYPECAST_NUM_T` (num_format_e format, num_at default_value)

Convert text_t to num_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (num_t : Treat the underlying text as a Number in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` num_t

`*TYPECAST_NVLIST_T` (`char` sep1, `char` sep2)

Convert text_t to nvlist_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (nvlist_t : Two character delimiters have to be provided when typecasting a Text object to a Name-Value List. The first delimited separates the name from the value. The second delimiter separates list items. For example typecast_nvlist_t('=', '&') handles a URL query string. The Text Mode has no effect on the character delimiters. For example if the current text mode is IGNORECASE and a delimiter is p then P will not be treated as a delimiter.)

`Parameters` (expressions not allowed) `:`

sep1- delimiter1

sep2- delimiter2

`Returns:` nvlist_t

`*TYPECAST_NVLIST_T` (`char` sep1, `char` sep2, `char` quote)

Convert text_t to nvlist_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (nvlist_t : Two character delimiters and quote-character have to be provided when typecasting a Text object to a Name-Value List that supports quote-character. The first delimited separates the name from the value. The second delimiter separates list items. The third value specifies the quote character. For example typecast_nvlist_t('=', ';', '"') handles a name-value list separated by semi-colons that allows quoting. The quote-character specifies that the value can occur within the quotes and the delimiters within the quote-characters should not be taken into account. The Text Mode has no effect on the character delimiters. For example if the current text mode is IGNORECASE and a delimiter is p then P will not be treated as a delimiter.)

`Parameters` (expressions not allowed) `:`

sep1- delimiter1

sep2- delimiter2

quote- quote-character.

`Returns:` nvlist_t

`*TYPECAST_PROTOCOL_BUFFER_T`

Convert text_t to protocol_buffer_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (protocol_buffer_t : gRPC Protocol Buffers interface)

`Returns:` protocol_buffer_t

`*TYPECAST_RADIUS_AVP_T`

Convert text_t to radius_avp_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (radius_avp_t : Operations that can be performed on the returned AVPs.

`Note:` An AVP can have multiple instances in a radius message. However, the system can access only the first 16 instances.

`Example:`

- To get the first value of AVP code 26 from a request, use: radius.REQ.AVP(26).VALUE(0).
- To get the fourth value of AVP code 26 from a request, use: radius.REQ.AVP(26).VALUE(3).

)

`Returns:` radius_avp_t

`*TYPECAST_RADIUS_AVP_VALUE_T`

Convert text_t to radius_avp_value_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (radius_avp_value_t : Provides operations to typecast RADIUS AVP value to Integer value or IP Address.)

`Returns:` radius_avp_value_t

`*TYPECAST_SEQ_TEXT_T`

Convert text_t to seq_text_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (seq_text_t : Represents the Text Sequence class.)

`Returns:` seq_text_t

`*TYPECAST_SERVICEPATH_T`

Convert text_t to servicepath_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (servicepath_t : Operations that can be performed on the service path.

`Example:`

- To get the name of the service path applicable to current subscriber, use: SUBSCRIBER.SERVICEPATH

- To determine If the service function is the next in the service path applicable to scubscriber, use: SUBSCRIBER.SERVICEPATH.IS_NEXT().

)

`Returns:` servicepath_t

`*TYPECAST_SIP_CALLID_HEADER_T`

Convert text_t to sip_callid_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_callid_header_t : This object provides operations for parsing the SIP callid header.)

`Returns:` sip_callid_header_t

`*TYPECAST_SIP_CONTENT_LENGTH_T`

Convert text_t to sip_content_length_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_content_length_t : The SIP.REQ.CONTENT_LENGTH or SIP.RES.CONTENT_LENGTH object can be treated as a SIP Header or as a Number. The numerical value for this object is derived from the value in the last instance of the Content-Length header.)

`Returns:` sip_content_length_t

`*TYPECAST_SIP_FROM_HEADER_T`

Convert text_t to sip_from_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_from_header_t : This object provides operations for parsing the SIP From header.)

`Returns:` sip_from_header_t

`*TYPECAST_SIP_HEADER_T` (text_t name)

Convert text_t to sip_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_header_t : When typecasting a Text object to SIP Header a header name must be provided.For example: SIP.REQ.HEADER("MyHdr").TYPECAST_SIP_HEADER_T("InHdr"))

`Parameters` (expressions not allowed) `:`

name- Header Name

`Returns:` sip_header_t

`*TYPECAST_SIP_HOSTNAME_T`

Convert text_t to sip_hostname_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_hostname_t : This object provides operations for parsing the SIP hostname as it appears at various places in the SIP protocol data. The format is abc.foo.com:5060.)

`Returns:` sip_hostname_t

`*TYPECAST_SIP_METHOD_T`

Convert text_t to sip_method_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_method_t : This object provides Text operations and SIP Request Method Enum operations on the SIP request method.)

`Returns:` sip_method_t

`*TYPECAST_SIP_TO_HEADER_T`

Convert text_t to sip_to_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_to_header_t : This object provides operations for parsing the SIP From header.)

`Returns:` sip_to_header_t

`*TYPECAST_SIP_URL_T`

Convert text_t to sip_url_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_url_t : SIP.REQ.URL provides operations for parsing and operating on the URL that is present in the first line of the SIP request header. The supported format is \[<protocol>://<hostname>\]<path>?<query>. The Text object backing a SIP URL object has the Text Mode set to URLENCODED by default.)

`Returns:` sip_url_t

`*TYPECAST_SIP_VERSION_T`

Convert text_t to sip_version_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_version_t : SIP.REQ.VERSION or SIP.RES.VERSION provide operations to extract SIP version information.)

`Returns:` sip_version_t

`*TYPECAST_SIP_VIA_HEADER_T`

Convert text_t to sip_via_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_via_header_t : This object provides operations for parsing the SIP Via header.)

`Returns:` sip_via_header_t

`*TYPECAST_SSLVPN_MODE_T`

Convert text_t to sslvpn_mode_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sslvpn_mode_t : This object provides Text operations and SSLVPN Mode Enum operations on the SSLVPN request method.)

`Returns:` sslvpn_mode_t

`*TYPECAST_SSL_TEXT_T` (text_t name)

Convert text_t to ssl_text_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ssl_text_t : Treat the underlying text object as SSL Text.)

`Parameters` (expressions not allowed) `:`

name- Name

`Returns:` ssl_text_t

`*TYPECAST_TCP_OPTIONS_T`

Convert text_t to tcp_options_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (tcp_options_t : TCP Protocol Options)

`Returns:` tcp_options_t

`*TYPECAST_TCP_OPTIONS_TYPE_T`

Convert text_t to tcp_options_type_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (tcp_options_type_t : TCP Protocol Options Type)

`Returns:` tcp_options_type_t

`*TYPECAST_TCP_REPEATER_OPTION_T`

Convert text_t to tcp_repeater_option_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (tcp_repeater_option_t : TCP Protocol Option : Repeater)

`Returns:` tcp_repeater_option_t

`*TYPECAST_TIME_AT`

Convert text_t to time_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (time_at : Treats a number value as number of seconds since GMT Jan 1 1970 0h 0m 0s.)

`Returns:` time_at

`*TYPECAST_TIME_LOCAL_AT`

Convert text_t to time_local_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (time_local_at : Treats a number value as number of seconds since GMT Jan 1 1970 0h 0m 0s as adjsuted for the local time zone.)

`Returns:` time_local_at

`*TYPECAST_TIME_T`

Convert text_t to time_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (time_t : This object treats a Text object as a date string. The formats supported are

1\. RFC822 :: Sun, 06 Nov 1994 08:49:37 GMT 2\. RFC850 :: Sunday, 06-Nov-94 08:49:37 GMT 3\. ASCTIME :: Sun Nov 6 08:49:37 1994 4\. ASCTIME like :: Sun Nov 6 08:49:37 1994 5\. ASCTIME like :: Sun Nov 06 08:49:37 1994 6\. Http Set-Cookie Expiry date :: Sun, 06-Nov-1994 08:49:37 GMT)

`Returns:` time_t

`*TYPECAST_UNSIGNED_LONG_AT`

Convert text_t to unsigned_long_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_at : Unsigned Long(64bit) Value)

`Returns:` unsigned_long_at

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error.)

`Parameters` (expressions not allowed) `:`

format- Format

`Returns:` unsigned_long_t

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format, ip_address_at default_value)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` unsigned_long_t

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format, unsigned_long_at default_value)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining

characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` unsigned_long_t

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format, num_at default_value)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` unsigned_long_t

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format, time_local_at default_value)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` unsigned_long_t

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format, time_at default_value)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` unsigned_long_t

`*TYPECAST_UNUM_TEXT_T`

Convert text_t to unum_text_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unum_text_t : Provides operations to treat the underlying OctectString as Binary String or unsigned long value .)

`Returns:` unum_text_t

`*TYPECAST_URL_CATEGORY_T`

Convert text_t to url_category_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (url_category_t : Retrieves URL category and attributes from an URL)

`Returns:` url_category_t

`*TYPECAST_VENDOR_SPEC_APPID_AVP_T`

Convert text_t to vendor_spec_appid_avp_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (vendor_spec_appid_avp_t : Retrieves AVPs that are nested in the grouped AVP Vendor-Specific-Application-Id (code 260). The nested AVPs are:

- Vendor-Id
- Auth-Application-Id
- Acct-Application-Id

For example, to retrieve the Auth-Application-Id AVP from the Vendor-Specific-Application-Id AVP:

- For requests: DIAMETER.REQ.VENDOR_SPECIFIC_APPLICATION_ID.AUTH_APPLICATION_ID
- For responses: DIAMETER.RES.VENDOR_SPECIFIC_APPLICATION_ID.AUTH_APPLICATION_ID

)

`Returns:` vendor_spec_appid_avp_t

`*TYPECAST_VENDOR_SPEC_RADIUS_AVP_T`

Convert text_t to vendor_spec_radius_avp_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (vendor_spec_radius_avp_t :

- Vendor-Id

To retrieve the Vendor-Id from the Vendor-Specific AVP:

- RADIUS.REQ.VENDOR_SPECIFIC.VENDORID

)

`Returns:` vendor_spec_radius_avp_t

`*UNQUOTE` (`char` c)

If selected text is quoted by character c, Remove character c from beginning and end.

For example: Say the selected text is / "foo xyz bar " /. Then on executing UNQUOTE("") the selected text will become /foo xyz bar / This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

c- Character

`Returns:` text_t

`*URLSET_MATCHES_ANY` (text_t urlset_name)

Results in Boolean TRUE value if and only if the Text matches any of the patterns that are specified in the urlset named by the string argument. The matching is case-insensitive for domains, but case-sensitive for paths. For example:

- HTTP.REQ.HOST.APPEND(HTTP.REQ.URL).URLSET_MATCHES_ANY("urlset_forbidden") returns true when the combined domain and URL matches any pattern in the urlset whose name is "urlset_forbidden".

`Parameters` (expressions not allowed) `:`

urlset_name- urlset name

`Returns:` bool_at

`*URL_CATEGORIZE` (`uint` min_reputation, `uint` max_reputation)

Returns the URL category for the supplied URL with the given minimum and maximum reputation score. Where a score of 5 is most risky and 1 is least risky. If either score is set to 0, that bound would be ignored. By specifying the reputation scores, the function will returned the category with the highest score (most risky) based on the bounds. If there was an error getting the category or if the URL is invalid then it will result in an Undef error. For example: HTTP.REQ.HOST.APPEND(HTTP.REQ.URL).URL_CATEGORIZE(0, 0) returns value when the combined domain and URL is looked up for the URL category with the highest reputation score (most risky).

`Parameters` (expressions not allowed) `:`

min_reputation- Minimum reputation score of URL category

max_reputation- Maximum reputation score of URL category

`Returns:` url_category_t

`*URL_RESERVED_CHARS_SAFE`

Converts URL reserved characters to corresponding '%XX' values and retains the rest. This is a read only operation.

```
Based on RFC3986, following are considered URL unreserved characters:

    Alpha-numeric characters: a-z, A-Z, 0-9

    Hyphen and underscore: "-", "_"

    Dot: "."

    Tilde: "~"
```

The rest are converted to %XX encoding, 'XX' is the hex-based representation of the input character. If the requirement is to encode all but URL safe characters, please consider using HTTP_URL_SAFE method.

`Returns:` text_t

`*XML_DECRYPT` (text_t certKeyName)

Decrypt the selected content, which was encrypted using the W3C XML Encryption standard.

`Parameters` (expressions not allowed) `:`

certKeyName- identifies the certkey object containing the RSA private key to be used to decrypt the bulk encryption key in the selected EncryptedData element.

`Returns:` text_t

`*XML_ENCRYPT` (text_t certKeyName, encrypt_method_e method)

Encrypt the selected cleartext using the W3C XML Encryption standard.

`Parameters` (expressions not allowed) `:`

certKeyName- identifies the certkey object containing an X.509 certificate with the RSA public key to be used to encrypt the generated bulk encryption key. Note that the certKey object need not, and usually will not, include the associated RSA private key.

method- specifies the bulk encryption method (rc4, des3, aes128, aes192, or aes256) used to encrypt the content.

`Returns:` text_t

`*XML_ENCRYPT` (text_t certKeyName, encrypt_method_e method, `uint` flags)

Encrypt the selected cleartext using the W3C XML Encryption standard.

`Parameters` (expressions not allowed) `:`

certKeyName- identifies the certkey object containing an X.509 certificate with the RSA public key to be used to encrypt the generated bulk encryption key. Note that the certKey object need not, and usually will not, include the associated RSA private key.

method- specifies the bulk encryption method (rc4, des3, aes128, aes192, or aes256) used to encrypt the content.

flags- optional bit mask to specify optional elements in the EncryptedData element. These are hints to tell the receiver what private key to use to decrypt the bulk encryption key, providing information from the certKey's X.509 certificate.

- 1 - include a KeyName element with the certKeyName;
- 2 - include a KeyValue element with the RSA public key from the certificate;
- 4 - include an X509IssuerSerial element with the certificate serial number and issuer DN;
- 8 - include an X509SubjectName element with the certificate subject DN;
- 16 - include an X509Certificate element with the entire certificate;

`Returns:` text_t

`*XPATH_HTML_WITH_MARKUP` (`xpath_str` xpathex)

Applies an XPath expression to the DOM for an HTML document and returns the selected node-set or string, including markup like element tags. node-sets are converted to strings using the standard XPath string conversion routine. The selected portion of the document can be used as the target for rewrite actions.

Examples: HTTP.REQ.BODY(1000).XPATH_HTML_WITH_MARKUP(xp%//md/head/title%) returns the <title> element in the document's <head> This can be used in a rewrite action to replace or delete the <title> element.

`Parameters` (expressions not allowed) `:`

xpathex- XPath Expression

`Returns:` text_t

`*XPATH_HTML` (`xpath_bool` xpathex)

Applies an XPath expression to the DOM for an HTML document and a boolean value.

Examples: HTTP.RES.BODY(1000).XPATH_HTML(xp%boolean(/md/head/meta)%) returns true if the <meta> element exists as a child of <head> element.

`Parameters` (expressions not allowed) `:`

xpathex- XPath Expression

`Returns:` bool_at

`*XPATH_HTML` (`xpath_double` xpathex)

Applies an XPath expression to the DOM for an HTML document and a double value.

Examples: HTTP.RES.BODY(1000).XPATH_HTML(xp%number(//video/@height)%) returns the numeric value of the height attribute of the first <video> element.

`Parameters` (expressions not allowed) `:`

xpathex- XPath Expression

`Returns:` double_at

`*XPATH_HTML` (`xpath_str` xpathex)

Applies an XPath expression to the DOM for an HTML document and returns the selected node-set or string. node-sets are converted to strings using the standard XPath string conversion routine.

Examples: HTTP.REQ.BODY(1000).XPATH_HTML(xp%//img/@src%) returns the string value of the src attribute of the first

HTTP_METHOD_E

This object represents one of the HTTP Request Methods.

Enumerations

GET

POST

HEAD

PUT

DELETE

OPTIONS

TRACE

CONNECT

UNKNOWN_METHOD

This topic lists the expressions that are provided by this class.

`EQ` (http_method_e m)

The result is Boolean TRUE if the input argument is equal to the HTTP Request Method represented by this object.

`Parameters` (expressions not allowed) `:`

m- Http Request Method Name

`Returns:` bool_at

HTTP_METHOD_T

This object provides Text operations and HTTP Request Method Enum operations on the HTTP request method.

This topic lists the expressions that are provided by this class.

`*Note` *: Expressions with the * symbol are inherited / promoted from text_t http_method_e

- `TYPECAST_TEXT_T`

  Convert http_method_t to text_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (text_t : Designates any piece of text.)

`Returns:` text_t

`*AFTER_REGEX` (`re` regex)

Selects the text after the portion that matches the given regular expression argument. The first match is returned when multiple matches occur in the text. The match may occur anywhere within the text - if you wish to "anchor" this, use "\^" at the start of the regex and/or "$" at the end of the regex. When the regular expression does not match the given string, a Text object of length of 0 is returned.

Example: HTTP.REQ.HEADER("etag").AFTER_REGEX(re/KX/) will select "DAPPER" from "KXDAPPER". This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

regex- Regular Expression

`Returns:` text_t

`*AFTER_STR_ANY` (text_t patset_name)

Selects the Text that is present after the first occurrence of any of the strings that are bound to the patset named by the string argument. If there is no match to any of the strings bound to the patset in the current Text object then the result Text object has 0 length. The patset cannot have strings

longer than 255 characters. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` text_t

`*AFTER_STR` (text_t s)

Selects the Text that is present after the first occurrence of the string argument. If there is no match for the argument in the current Text then the result Text object has 0 length. The input string cannot be bigger than 255 characters. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*APPEND` (bool_at b)

Appends the given boolean's string representation to the current string.

`Parameters``:`

b- the boolean value to append.

`Returns:` text_t

`*APPEND` (double_at i)

Appends the given double's string representation to the current string.

`Parameters``:`

i- the double value to append.

`Returns:` text_t

`*APPEND` (ip_address_at addr)

Appends the given IPv4's string representation to the current string.

`Parameters``:`

addr- the IPv4 address to append.

`Returns:` text_t

`*APPEND` (num_at i)

Appends the given number's string representation to the current string.

`Parameters``:`

i- the number value to append.

`Returns:` text_t

`*APPEND` (time_local_at t)

Appends the given time's string representation to the current string.

`Parameters``:`

t- the time value to append.

`Returns:` text_t

`*APPEND` (time_at t)

Appends the given time's string representation to the current string.

`Parameters``:`

t- the time value to append.

`Returns:` text_t

`*APPEND` (unsigned_long_at i)

Appends the given unsigned long's string representation to the current string.

`Parameters``:`

i- the unsigned long value to append.

`Returns:` text_t

`*APPEND` (ipv6_address_at addr)

Appends the given IPv6's string representation to the current string.

`Parameters``:`

addr- the IPv6 address to append.

`Returns:` text_t

`*APPEND` (ipv6_subnet_at addr)

Appends the given IPv6 subnet's string representation to the current string.

`Parameters``:`

addr- the IPv6 subnet to append.

`Returns:` text_t

`*APPEND` (mac_address_at addr)

Appends the given MAC's string representation to the current string.

`Parameters``:`

addr- the MAC address to append.

`Returns:` text_t

`*APPEND` (text_t str)

Appends the given string to the current string.

`Parameters``:`

str- the string to append.

`Returns:` text_t

`*APPEND` (time_at t)

Appends the given time's string representation to the current string.

`Parameters``:`

t- the time value to append.

`Returns:` text_t

`*B64DECODE`

Decodes the selected text using base64 decoding.

For example, the string "TWFu" is converted to "Man"

`Returns:` text_t

`*B64ENCODE`

Encodes the selected text using base64 encoding.

For example, the string "Man" is converted to "TWFu"

`Returns:` text_t

`*BEFORE_REGEX` (`re` regex)

Selects the text before the portion that matches the given regular expression argument. The first match is returned when multiple matches occur in the text. The match may occur anywhere within the text - if you wish to "anchor" this, use "\^" at the start of the regex and/or "$" at the end of the regex. When the regular expression does not match the given string, a Text object of length of 0 is returned.

For example: HTTP.RES.HEADER("content-type").BEFORE_REGEX(re#/#) will select "text" from "text/plain". This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

regex- Regular Expression

`Returns:` text_t

`*BEFORE_STR_ANY` (text_t patset_name)

Selects the Text that is present before the first occurrence of any of the strings that are bound to the patset or datasetnamed by the string argument. If there is no match to any of the strings bound to the patset in the current Text object then the result Text object has 0 length. The patset cannot have strings longer than 255 characters. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` text_t

`*BEFORE_STR` (text_t s)

Selects the Text that is present before the first occurrence of the string argument. If there is no match for the argument in the current Text object then the result Text object has 0 length. The input string cannot be bigger than 255 characters. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*BETWEEN` (text_t start, text_t end)

Results in Boolean TRUE value if length of the Text object is greater than or equal to the sum of the Start and End argument lengths and if the prefix of the Text object matches the Start string argument and if the Suffix of the Text object matches the End string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

start- Start

end- End

`Returns:` bool_at

`*BIN_DECODE` (binary_encoding_e encoding)

Decode the encoded input into its original byte sequence. An incorrectly enooded input will result in an Undef error.

`Parameters` (expressions not allowed) `:`

encoding- specifies how the bytes are encoded.

`Returns:` text_t

`*BIN_ENCODE` (binary_encoding_e encoding)

Encode the input byte sequence. Note that BIN_ENCODE(hex_colons) is equivalent to BLOB_TO_HEX().

`Parameters` (expressions not allowed) `:`

encoding- specifies how the bytes are to be encoded.

`Returns:` text_t

`*BLOB_TO_HEX`

Convert to hexadecimal representation and select text.

For example, the byte string abc is converted to 61:62:63.

`Returns:` text_t

`*COMPARE` (text_t s)

Results in a Number Value which is the result of comparison of the input argument with the Text object. The result is greater than 0 if the Text object is lexicographically greater than the argument. The result is 0 if the Text object and the argument match. The result is less than 0 if the Text object is lexicographically lesser than the argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` num_at

`*CONTAINS_ANY` (text_t patset_name)

Results in Boolean TRUE value if the Text contains any of the strings that are bound to the patset or dataset named by the string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` bool_at

`*CONTAINS_INDEX` (text_t patset_name)

Returns the numerical index of the matching string, if the Text contains any of the strings that are bound to the patset or dataset named by the string argument. Returns 0 if there is no match. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` num_at

`*CONTAINS` (text_t s)

Results in Boolean TRUE value if the Text contains the string given in the argument. The input string cannot be bigger than 255 characters. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*CRC32`

Returns a 32-bit integer computed by applying a CRC (cyclic redundancy check) function to the selected text. This is the CRC function used by Ethernet, MPEG-2, PKZIP, GZIP, PNG, and many other applications. For example, the expression to compute the CRC value of the (first 1000 bytes of the) body of an HTTP request is: HTTP.REQ.BODY(1000).CRC32

`Returns:` num_at

`*DECODE_USING_TEXT_MODE`

Decodes the selected text using the currently configured text encoding methods like URLENCODED, BACKSLASH_ENCODED, PLUS_AS_SPACE, NOURLENCODED, NO_BACKSLASH_ENCODED and NO_PLUS_AS_SPACE. Text encoding methods are set using SET_TEXT_MODE method.

`Returns:` text_t

`*DECRYPT`

Decrypt the selected base64-encoded ciphertext using the configured encryptionParams.

`Returns:` text_t

`*DECRYPT` (binary_encoding_e in_encoding)

Decrypt the selected ciphertext using the configured encryptionParams.

`Parameters` (expressions not allowed) `:`

in_encoding- specifies how the input ciphertext is encoded. If the ciphertext is not encoded as specified, causes an Undef error.

`Returns:` text_t

`*DECRYPT` (text_t encryptionKey)

Decrypt the selected base64-encoded encrypted bytes using the configured encryption key.

`Parameters` (expressions not allowed) `:`

encryptionKey- identifies the encryptionKey object to provide the cipher method, mode, padding, key, encrypted format and optional initialization vector (IV).

`Returns:` text_t

`*DECRYPT` (text_t encryptionKey, binary_encoding_e in_encoding)

Decrypt the selected base64-encoded encrypted bytes using the configured encryption key.

`Parameters` (expressions not allowed) `:`

encryptionKey- identifies the encryptionKey object to provide the cipher method, mode, padding, key, encrypted format, and optional initialization vector (IV).

in_encoding- specifies how the input ciphertext is encoded. If the ciphertext is not encoded as specified, causes an Undef error.

`Returns:` text_t

`*DIGEST` (digest_method_e method)

Returns a byte sequence computed by applying the the specified message digest method to the selected text.

`Parameters` (expressions not allowed) `:`

method- digest method to apply to the input text

`Returns:` text_t

`*ENCRYPT`

Encrypt the selected plaintext bytes using the configured encryptionParams. The resulting ciphertext is base64-encoded.

`Returns:` text_t

`*ENCRYPT` (binary_encoding_e out_encoding)

Encrypt the selected plaintext bytes using the configured encryptionParams.

`Parameters` (expressions not allowed) `:`

out_encoding- specifies how the resulting ciphertext is encoded.

`Returns:` text_t

`*ENCRYPT` (text_t encryptionKey)

Encrypt the selected cleartext bytes using the configured encryption key.

`Parameters` (expressions not allowed) `:`

encryptionKey- identifies the encryptionKey object to provide the cipher method, mode, padding, key, encrypted format and optional initialization vector (IV).

`Returns:` text_t

`*ENCRYPT` (text_t encryptionKey, binary_encoding_e out_encoding)

Encrypt the selected cleartext bytes using the configured encryption key.

`Parameters` (expressions not allowed) `:`

encryptionKey- identifies the encryptionKey object to provide the cipher method, mode, padding, key, encrypted format and optional initialization vector (IV).

out_encoding- specifies how the resulting ciphertext is encoded.

`Returns:` text_t

`*ENDSWITH_ANY` (text_t patset_name)

Results in Boolean TRUE value if the Text ends with any of the strings that are bound to the patset or dataset named by the string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` bool_at

`*ENDSWITH_INDEX` (text_t patset_name)

Returns the numerical index of the matching string, if the Text ends with any of the strings that are bound to the patset or dataset named by the string argument. Returns 0 if there is no match. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` num_at

`*ENDSWITH` (text_t end)

Results in Boolean TRUE value if a suffix of the Text object matches the string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

end- String

`Returns:` bool_at

`*EQUALS_ANY` (text_t patset_name)

Results in Boolean TRUE value if the Text equals any of the strings that are bound to the patset or dataset named by the string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` bool_at

`*EQUALS_INDEX` (text_t patset_name)

Returns the numerical index of the matching string, if the Text equals any of the strings that are bound to the patset or dataset named by the string argument. Returns 0 if there is no match. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` num_at

`*EQ` (http_method_e m)

The result is Boolean TRUE if the input argument is equal to the HTTP Request Method represented by this object.

`Parameters` (expressions not allowed) `:`

m- Http Request Method Name

`Returns:` bool_at

`*EQ` (text_t s)

Results in Boolean TRUE value if the Text object matches the input argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*GET_SIGNED16` (`uint` n, endian_e endianness)

Get the 16-bit signed binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

endianness- Select little or big endian

`Returns:` num_at

`*GET_SIGNED32` (`uint` n, endian_e endianness)

Get the 32-bit signed binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

endianness- Select little or big endian

`Returns:` num_at

`*GET_SIGNED8` (`uint` n)

Get the 8-bit signed binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

`Returns:` num_at

`*GET_UNSIGNED16` (`uint` n, endian_e endianness)

Get the 16-bit unsigned binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

endianness- Select little or big endian

`Returns:` num_at

`*GET_UNSIGNED32` (`uint` n, endian_e endianness)

Get the 32-bit unsigned binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

endianness- Select little or big endian

`Returns:` unsigned_long_at

`*GET_UNSIGNED64` (`uint` n, endian_e endianness)

Get the 64-bit unsigned binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

endianness- Select little or big endian

`Returns:` unsigned_long_at

`*GET_UNSIGNED8` (`uint` n)

Get the 8-bit unsigned binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

`Returns:` num_at

`*GET_URLSET_METADATA` (text_t urlset_name)

Returns metadata value corresponding to pattern in the urlset. The matching is case-insensitive for domains, but case-sensitive for paths. If no pattern is matched within the urlset, the return value is a NULL string. For example:

- HTTP.REQ.HOST.APPEND(HTTP.REQ.URL).GET_URLSET_METADATA("urlset_forbidden") returns value when the combined domain and URL is looked up in the urlset whose name is "urlset_forbidden".

`Parameters` (expressions not allowed) `:`

urlset_name- urlset name

`Returns:` text_t

`*GE` (text_t s)

Results in Boolean TRUE value if the Text object is greater than or equal to the input argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*GRPC`

Interprets a text_t string as a Protocol Buffer (protocol_buffer_t type). Example: HTTP.REQ.BODY(1000).GRPC.STRING(1).EQ("bookname")

`Returns:` protocol_buffer_t

`*GT` (text_t s)

Results in Boolean TRUE value if the Text object is greater than the input argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*HASH`

Returns a positive 31 bit integer value computed by applying a proprietary NetScaler hash function to the selected text. This function is not case- sensitive and ignores whitespaces. For example, applying the HASH function to two strings "Ab c" and "abc" would produce the same value. This function should not be used for security purposes; use instead the DIGEST function with one of the standard digest methods.

`Returns:` num_at

`*HMAC` (text_t hmacKey)

Returns a byte sequence computed by applying the HMAC (Hash Message Authenticastion Code) function to the selected text using the configured HMAC key.

`Parameters` (expressions not allowed)`:`

hmacKey- indentifies the hmacKey object to provide the digest (hash) method and the key.

`Returns:` text_t

`*HMAC` (text_t hmacKey, binary_encoding_e out_encoding)

Returns a byte sequence computed by applying the HMAC (Hash Message Authenticastion Code) function to the selected text using the configured HMAC key .

`Parameters` (expressions not allowed)`:`

hmacKey- indentifies the hmacKey object to provide the digest (hash) method and the key.

out_encoding- specifies how the resulting HMAC is encoded.

`Returns:` text_t

`*HTML_XML_SAFE`

Apply XML safe transform and select text.

Converts '<', '>' and '&' in the input text to '<', '>' and '&' respectively; other characters in the input are not modified. This transform safeguards against XSS based attacks. This is a read only operation.

`Returns:` text_t

`*HTTP_HEADER_SAFE`

Apply Header safe transform and select text. Converts all new line ('\\n') characters present in the input text to '%0A' so that they can safely be used in HTTP headers. This transform safeguards against response-splitting attacks. This is a read only operation.

`Returns:` text_t

`*HTTP_URL_SAFE`

Apply URL safe transform and select text. Converts URL unsafe characters to corresponding '%xx' values and retains the rest. This is a read only operation.

```
Based on RFC2396, following are considered URL safe characters:

    Alpha-numeric characters: a-z, A-Z, 0-9

    Hyphen and underscore: "-", "_"

    Dot: "."

    Exclamation mark: "!"

    Tilde: "~"

    Asterix: "&ast;"

    Single quote: "'"

    Open and close parentheses: "(", ")"

    Semi-colon: ";"
```

```
    Colon: ":"

    At symbol: "@"

    Question mark: "?"

    Equals: "="

    Dollar: "$"

    Percent: "%"

    Ampersand: "&"

    Plus: "+"

    Comma: ","

    Forward slash: ".html"
```

The rest are converted to %XX encoding, 'XX' is the hex-based representation of the input character. If the requirement is to encode all but URL unreserved characters, please consider using URL_RESERVED_CHARS_SAFE method.

`Returns:` text_t

`*IS_BOOL_AT`

Results in Boolean TRUE value if the Text is of boolean type.

`Returns:` bool_at

`*IS_DOUBLE_AT`

Results in Boolean TRUE value if the Text is of double data type.

`Returns:` bool_at

`*IS_IPV6_AT`

Results in Boolean TRUE value if the Text is of IPv6 data type.

`Returns:` bool_at

`*IS_IPV6_SUBNET_AT`

Results in Boolean TRUE value if the Text is of IPv6 subnet data type.

`Returns:` bool_at

`*IS_IP_AT`

Results in Boolean TRUE value if the Text is of IPv4 data type.

`Returns:` bool_at

`*IS_MAC_ADDRESS_AT`

Results in Boolean TRUE value if the Text is of mac address data type.

`Returns:` bool_at

`*IS_NUM_AT`

Results in Boolean TRUE value if the Text is of number type.

`Returns:` bool_at

`*IS_NUM_AT` (num_format_e format)

Results in Boolean TRUE value if the Text is of number type with given input base.

`Parameters` (expressions not allowed) `:`

format- number format

`Returns:` bool_at

`*IS_STRINGMAP_KEY` (text_t string_map_name)

Returns true if the string that it operates on is present in the string map. Text mode IGNORECASE, NOIGNORECASE - controls whether key lookup in string map is case sensitive or not. For example:

- HTTP.REQ.URL.IS_STRINGMAP_KEY("url_stringmap") returns true if value of HTTP.REQ.URL is present as key in the string map whose name is "url_stringmap".
- HTTP.REQ.URL.SET_TEXT_MODE(IGNORECASE). IS_STRINGMAP_KEY("url_stringmap") returns true if value of HTTP.REQ.URL is present as key in the string map whose name is "url_stringmap". Key lookup in this case is done case-insensitively.

`Parameters` (expressions not allowed) `:`

string_map_name- identifies the string map.

`Returns:` bool_at

`*IS_TIME_AT`

Results in Boolean TRUE if the Text follows any of the standard time formats given below, otherwise false. Tue, 05 Nov 1994 08:12:31 GMT RFC822 Tuesday, 05-Nov-94 08:12:31 GMT RFC850 Tue Nov 4 08:12:31 1994 asctime

`Returns:` bool_at

`*IS_UNSIGNED_LONG_AT`

Results in Boolean TRUE value if the Text is of unsigned long data type.

`Returns:` bool_at

`*IS_UNSIGNED_LONG_AT` (num_format_e format)

Results in Boolean TRUE value if the Text is of unsigned long data type with given input base.

`Parameters` (expressions not allowed) `:`

format- number format

`Returns:` bool_at

`*JWT_VERIFY_CERTKEY` (text_t certkey_name)

Verifies the signature on the input JSON Web Token (JWT), using the RSA public key in the X.509 certificate in the specified certkey object. The token has the format HEADER.PAYLOAD.SIGNATURE where

- HEADER is a base64-encoded JSON structure indicating a signature algorithm and token type, e.g.'{"alg":"RS256","typ":"JWT"}'
- PAYLOAD is a base64-encoded JSON structure with asserted claims, e.g. '{"loggedInAs":"admin","iat":1422779638}'
- SIGNATURE is the base64-encoded bytes for the signature on HEADER.PAYLOAD.

Returns true if the signature is verified for the header and payload using the specified public key; false if the signature is not verified

`Parameters``:`

certkey_name- identifies the certkey object containing an X.509 certificate holding the RSA public key. Results in an Undef error if the certkey object does not exist or does not contain an X.509 certificate with an RSA public key, if the token is not correctly formatted, or if the verification operation cannot complete.

`Returns:` bool_at

`*JWT_VERIFY_XML` (text_t xml_pkey)

Verifies the signature on the input JSON Web Token (JWT), using the RSA public key supplied by the specified XML element. The token has the format HEADER.PAYLOAD.SIGNATURE where

- HEADER is a base64-encoded JSON structure indicating a signature algorithm and token type, e.g.'{"alg":"RS256","typ":"JWT"}'
- PAYLOAD is a base64-encoded JSON structure with asserted claims, e.g. '{"loggedInAs":"admin","iat":1422779638}'
- SIGNATURE is the base64-encoded bytes for the signature on HEADER.PAYLOAD.

Returns true if the signature is verified for the header and payload using the specified public key; false if the signature is not verified

`Parameters``:`

xml_pkey- an expression that supplies an <RSAKeyValue> element with the public key. Results in an Undef error if the XML element is invalid or does not correctly specify an RSA public key, if the token is not correctly formatted, or if the verification operation cannot complete.

`Returns:` bool_at

`*LENGTH`

Results in a Number Value that is the number of characters (not bytes) in the Text object.

`Returns:` num_at

`*LE` (text_t s)

Results in Boolean TRUE value if the Text object is less than or equal to the input argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*LOCATION_LONG`

Get the location qualifier from CLIENT.IP.SRC.LOCATION.GET(n) (ISO short name) and then convert it to human readable long name. This conversion is valid only for country names. Correct Country qualifier value (number) in GET(n) is left up to the user as qualifiers are user configurable. Expression example: CLIENT.IP.SRC.LOCATION.GET(1).LOCATION_LONG For example: Data from each expression CLIENT.IP.SRC.LOCATION: NA.US.California.SantaClara.*.* CLIENT.IP.SRC.LOCATION.GET(1): US CLIENT.IP.SRC.LOCATION.GET(1).LOCATION_LONG: United States

`Returns:` text_t

`*LT` (text_t s)

Results in Boolean TRUE value if the Text object is less than the input argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*MAP_STRING_DEFAULT_TO_KEY` (text_t string_map_name)

Returns the value corresponding to the key in the string map. This is similar to the MAP_STRING method, but if the key is not present then instead of returning a null string, it returns the key itself. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

string_map_name- identifies the string map.

`Returns:` text_t

`*MAP_STRING` (text_t string_map_name)

Returns value corresponding to key in the string map. Key is the string that it is given as input. Text mode IGNORECASE, NOIGNORECASE - controls whether key lookup in string map is case sensitive or not. For example:

- HTTP.REQ.URL.MAP_STRING("url_stringmap") returns value when the value of HTTP.REQ.URL is used as key in the string map whose name is "url_stringmap".
- HTTP.REQ.URL.SET_TEXT_MODE(IGNORECASE). MAP_STRING("url_stringmap") returns value when the value of HTTP.REQ.URL is used as key in the string map whose name is "url_stringmap". Key lookup in this case is done case-insensitively.

`Parameters` (expressions not allowed) `:`

string_map_name- identifies the string map.

`Returns:` text_t

`*MARK_SAFE`

Mark the PIXL expression safe without applying any safe transform.

`Returns:` text_t

`*MAX` (text_t s)

Compares the string argument with the current string and returns the max string. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*MIN` (text_t s)

Compares the string argument with the current string and returns the min string. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*NE` (text_t s)

Results in Boolean TRUE value if the Text object is not equal to the input argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*NORMALIZE_URL`

Normalize URL. Normalizes a URL by doing "percent" decoding. See the description for URLENCODED in the SET_TEXT_MODE function. This performs the equivalent of SET_TEXT_MODE(URLENCODED).DECODE_USING_TEXT_MODE, except that it does not change the value of the current text mode.

`Returns:` text_t

`*PKEY_ENCRYPT_PEM_NO_PADDING` (text_t pem_pkey)

Encrypts the input text using the RSA public key provided by the PEM string and RSA_NO_PADDING padding method. The input text to be encrypted cannot be longer than the public key length minus 11 bytes for padding. For example, for a 1024-bit (128 byte) key, the input text cannot be longer than 128 - 11 = 117 bytes. An Undef error will occur if the input text is too long. A null input will also cause an Undef error. Returns the (unencoded binary) encrypted text, which is typically base-64 encoded for use in a message.

`Parameters``:`

pem_pkey- a text expression that supplies a RSA public key in the PEM format. If the text value is not a valid PEM RSA PUBLIC KEY encoding, an Undef error will occur. Example (a 1024-bit public key):

```
"-----BEGIN RSA PUBLIC KEY-----" +

"MIGJAoGBAKl5vgQEj73Kxp+9yn1v5gPR1pnc4oLM2a0kaWwBOsB6rzCIy6znwnvw" +

"CY1xRvQhRlJSAyJbloL7wZFIJ2FOR8Cz+8ZQWXU2syG+udi4EnWqLgFYowF9zK+o" +

"79az597eNPAjsHZ/C2oL/+6qY5a/f1z8bQPrHC4GpFfAEJhh/+NnAgMBAAE=" +

"-----END RSA PUBLIC KEY-----"
```

`Returns:` text_t

`*PKEY_ENCRYPT_PEM` (text_t pem_pkey)

Encrypts the input text using the RSA public key provided by the PEM string and the RSA_PKCS1_PADDING padding method. The input text to be encrypted cannot be longer than the public key length minus 11 bytes for padding. For example, for a 1024-bit (128 byte) key, the input text cannot be longer than 128 - 11 = 117 bytes. An Undef error will occur if the input text is too long. A null input will also cause an Undef error. Returns the (unencoded binary) encrypted text, which is typically base-64 encoded for use in a message.

`Parameters``:`

pem_pkey- a text expression that supplies a RSA public key in the PEM format. If the text value is not a valid PEM RSA PUBLIC KEY encoding, an Undef error will occur. Example (a 1024-bit public key):

```
"-----BEGIN RSA PUBLIC KEY-----" +

"MIGJAoGBAKl5vgQEj73Kxp+9yn1v5gPR1pnc4oLM2a0kaWwBOsB6rzCIy6znwnvw" +

"CY1xRvQhRlJSAyJbloL7wZFIJ2FOR8Cz+8ZQWXU2syG+udi4EnWqLgFYowF9zK+o" +

"79az597eNPAjsHZ/C2oL/+6qY5a/f1z8bQPrHC4GpFfAEJhh/+NnAgMBAAE=" +

"-----END RSA PUBLIC KEY-----"
```

`Returns:` text_t

`*PKEY_SIGN_CERTKEY` (text_t certkey_name)

Generates a binary digital signature using the SHA-256 message digest function and an RSA private key from the specified SSL certKey object.

`Parameters``:`

certkey_name- identifies the configured certKey object. Results in an Undef error if the certkey object does not exist or does not contain an RSA private key, or if the signing operation cannot complete.

`Returns:` text_t

`*PKEY_SIGN_XML` (text_t xml_pkey)

Generates a binary digital signature using the SHA-256 message digest function and an RSA private key from the specified XML element.

`Parameters``:`

xml_pkey- an expression that supplies an <RSAKeyValue> element with the private key. Example: <RSAKeyValue> <Modulus>qXm+BASPvcrGn73KfW/mA9HWmdzigszZrSRpbAE6wHqvMIjLrOfCe/AJjXFG9CFGUlIDIluWgvvBkUgnYU5HwLP7xlBZdTazIb652LgSdaouAVijAX3Mr6jv1rPn3t408COwdn8Lagv/7qpjlr9/XPxtA+scLgakV8AQmGH/42c=</Modulus> <Exponent>AQAB</Exponent>"zNjysxcIJV/J9cTpIgPp2/x1IXHT5GTH8OMuNad0qtRSLjU1QYUmmkm9QcJJAN+7h8FEXWGabySUzBrHj/IEbw==" <DP>QavUDQLLQpnPJXtVAo6CYhxOMCd68mwTxYKKNLjmC0pd54SFHllTLPE1FZU5EjK6q3nCeijonpfH+XXDP> <DQ>EiXOKouJzzXTQJC3TqomF7Uf81yQNxWumOqnd11kepXgyfMwyqMvLlAGEkNSEF/Bz18R3Wv+MIZ/IC3nLBt2xQ==</DQ> <InverseQ>ocuCmz36CP+N2aGqxaU+BKD5+3RLgRq9LFhULEz2jKx0iV9r76jsAxn3sLcTYYO9eqRPy2cz74AUnw==</InverseQ> <D>fTBD773a3GzcmgVdfZlaBLpN1ux2mf5uUVrTUQf7eVFm9egm4/tzC5A9zjC+I/oscwTH8epL3UfRLdtp05Q6pWfJBXEnGo0QmOFFBK4pLx/5JJpPGZ69ovDFEVOUHyiCfKE/g97T4WX3us0nFe1272zwGlHarM1YYwvfeE08UdE=</D> </RSAKeyValue> Results in an Undef error if the XML element is invalid or does not correctly specify an RSA private key, or if the signing operation cannot complete.

`Returns:` text_t

`*PKEY_VERIFY_CERTKEY` (text_t certkey_name, text_t signature)

Verifies if the input text matches the specified signature generated using the SHA-256 messge digest function and the RSA private key associated with the specified RSA public key in the X.509 certificate in the specified certKey object. Returns true if the signature is verified, false otherwise.

`Parameters``:`

certkey_name- identifies the certkey object containing an X.509 certificate holding the RSA public key.

signature- the binary signature. Results in an Undef error if the certkey object does not exist or does not contain an X.509 certificate with an RSA public key, or if the verification operation cannot complete.

`Returns:` bool_at

`*PKEY_VERIFY_XML` (text_t xml_pkey, text_t signature)

Verifies if the input text matches the specified signature generated using the SHA-256 messge digest function and the RSA private key associated with the RSA public key supplied by the specified XML element. Returns true if the signature is verified, false otherwise.

`Parameters``:`

xml_pkey- an expression that supplies an <RSAKeyVAlue> element with the public key. Example: <RSAKeyValue> <Modulus>qXm+BASPvcrGn73KfW/mA9HWmdzigszZrSRpbAE6wHqvMIjLrOfCe/AJjXFG9CFGUlIDIluWgvvBkUgnYU5HwLP7xlBZdTazIb652LgSdaouAVijAX3Mr6jv1rPn3t408COwdn8Lagv/7qpjlr9/XPxtA+scLgakV8AQmGH/42c=</Modulus> <Exponent>AQAB</Exponent> </RSAKeyValue>

signature- the binary signature. Results in an Undef error if the XML element is invalid or does not correctly specify an RSA public key, or if the verification operation cannot complete.

`Returns:` bool_at

`*PREFIX` (`char` c, `uint` i)

Select a prefix of the Text. The selected prefix is the longest prefix that has at most Count (2nd argument) occurrences of character in the 1st argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

c- Character

i- Count

`Returns:` text_t

`*PREFIX` (`uint` i)

Select a prefix of the Text. The length of the prefix is equal to the number in the argument. If there aren't enough characters in the Text object then the entire Text is selected.

`Parameters``:`

i- Prefix Length

`Returns:` text_t

`*REGEX_MATCH` (`re` regex)

Returns TRUE if and only if the text contains at least one match of the regular expression argument. The match may occur anywhere within the text - if you wish to "anchor" this, use "\^" at the start of the regex and/or "$" at the end of the regex.

The regular expression has to be of the format: `re<delimiter>regular expression<same delimiter>`

The regular expression cannot be bigger than 1499 characters.

The regular expression should be acceptable by the PCRE regular expression library. Look at http://www.pcre.org/pcre.txt for documentation on the regular expression syntax. In particular, look at the pcrepattern man page.

There are some differences in the allowed syntax w.r.t PCRE syntax. Backreferences are not allowed. It is recommended not to use recursive regular expressions. The dot metacharacter matches newlines also. Unicode is not supported. SET_TEXT_MODE(IGNORECASE) overrides the (?i) internal option specified in the regular expression.

The PCRE library configuration can be seen in the system log, after executing 'nsapimgr -B" call ns_pixl_regex_show_config()"' at the shell prompt.

Some examples:

- HTTP.REQ.HOSTNAME.REGEX_MATCH(re/\[\[:alpha:\]\]+(abc){2,3}/)
- HTTP.REQ.URL.SET_TEXT_MODE(URLENCODED).REGEX_MATCH(re#(a*b+c*)#)
- HTTP.REQ.URL.REGEX_MATCH(re/a(?i)b/) matches ab and aB
- HTTP.REQ.URL.SET_TEXT_MODE(IGNORECASE).REGEX_MATCH(re/ab/) matches ab, aB, Ab and AB
- HTTP.REQ.BODY.REGEX_MATCH(re/(?ixm) (\^ab (.*) cd$) /) does a case-insensitive, multiline match where the dot metacharacter matches newline also. The regex itself can contain whitespace which will be ignored during the matching (x - extended regex).

This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

regex- Regular Expression

`Returns:` bool_at

`*REGEX_REPLACE` (`re` regex, text_t replacement, replacemode_e mode)

Selects the text that matches the given regular expression argument and replaces it with the the text given in the second argument. The third argument specifies whether the first match is only replaced when multiple matches occur in the text or all matches are replaced. The match may occur anywhere within the text - if you wish to "anchor" this, use "\^" at the start of the regex and/or "$" at the end of the regex. When the regular expression does not match the given string then the same string is returned.

For example: HTTP.RES.BODY(999).REGEX_REPLACE(re!\\bpassword:\\s*\\b!, "password: ***", ALL) will replace all occurrences of "password:" with "password: ***" This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

regex- Regular Expression

replacement- String to replace the match

mode- Mode of replacement

`Returns:` text_t

`*REGEX_SELECT` (`re` regex)

Selects the text that matches the given regular expression argument. The first match is returned when multiple matches occur in the text. The match may occur anywhere within the text - if you wish to "anchor" this, use "\^" at the start of the regex and/or "$" at the end of the regex. When the regular expression does not match the given string, a Text object of length of 0 is returned.

For example: HTTP.REQ.HEADER("via").REGEX_SELECT(re!NS-CACHE-\\d\\.\\d:\\s*\\d{1,3}!) will select "NS-CACHE-7.0: 70" This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

regex- Regular Expression

`Returns:` text_t

`*REPEAT` (`uint` i)

Produces a string which contains 'i' sequential copies of the input string.

`Parameters``:`

i- the number of times to repeat the string (0 or more)

`Returns:` text_t

`*SET_CHAR_SET` (charset_e charset)

Set the character set to use for subsequent functions that use text.

`Parameters` (expressions not allowed)`:`

charset- Character Set

`Returns:` http_method_t

`*SET_TEXT_MODE` (textmode_e mode)

The mode setting of a Text object controls the behavior of many Text operations. The Text mode settings may also control the behavior of some operations in objects (like List) that build upon the Text object. IGNORECASE, NOIGNORECASE - controls whether string comparison is case sensitive or not. URLENCODED - If set then all Text operations are carried out after translating all %HH or %uHHHH encodings in the underlying byte stream. 1. %HH will be translated to the character Y where HH denotes the ascii value of character Y in hexadecimal. For example, the encoded text "http%3a/.html" will be decoded to "http:/.html" 2. %uWWHH will be translated to the character sequence YZ where WW denotes the ascii value of character Y in hexadecimal and HH denotes the ascii value of character Z in hexadecimal. For example, the encoded text "http%u3a2f.html" and "http%u003a/.html" will both be decoded to"http:/.html" NOURLENCODED - Indicates that no percent encodings are present in the Text object. No percent decoding will be performed on the Text object. PLUS_AS_SPACE - If set then all Text operations are carried out after converting occurrences of the plus character to whitespace. For example, the text "hello+world" will be decoded to "hello world" NO_PLUS_AS_SPACE - If set, then the plus character will not be converted to whitespace in the Text object. BACKSLASH_ENCODED - If set, then all Text operations are carried out after performing the following operations: 1. \\XXX will be translated to the character Y where XXX denotes the ascii value of character Y in octal. The valid range of octal values for this type of encoding is \\0 to \\377. For example, the encoded text "http\\72/.html" and "http\\072/.html" will both be decoded to "http:/.html" 2. \\xHH will be translated to the character Y where HH denotes the ascii value of character Y in hexadecimal. For example, the encoded text "http\\x3a/.html" will be decoded to "http:/.html" 3. \\\\uWWXX will be translated to the character sequence YZ where WW denotes the ascii value of character Y in hexadecimal and XX denotes the ascii value of character Z in hexadecimal. For example, the encoded text

"http%u3a2f.html" and "http%u003a/.html" will both be decoded to"http:/.html" 4. Occurences of "\ \b", "\\n", "\\t", "\\f" and "\\r" are translated to the corresponding ascii characters. NO_BACKSLASH_ENCODED - If set, then backslash decoding will not be performed on the Text object. BAD_ENCODE_RAISE_UNDEF - If set, then UNDEF is raised if either the URLENCODED or BACKSLASH_ENCODED mode is set and a bad encoding corresponding to the specified encoding mode is encountered. NO_BAD_ENCODE_RAISE_UNDEF - If set, then UNDEF will not be raised when a bad encoding is encountered in the Text object. The Text operations operate on characters (as opposed to operating on bytes). By default a single byte represents a character using the ASCII encoding. But if URLENCODED mode is set then 3 bytes may represent a character. A PREFIX(3) operation will select the first 3 characters in the Text object. That means it may select up to 9 bytes for URLENCODED Text object. In the case of multibyte decodings as a result of %uXXXX or \\\\uXXXX, Text operations which attempt to treat the multiple decoded bytes as distinct characters are not allowed.

`Parameters` (expressions not allowed) `:`

mode- Text Mode

`Returns:` http_method_t

`*SKIP` (`char` c, `uint` i)

Select the Text after skipping over a prefix of the current Text. The skipped over prefix is the longest prefix that has at most Count (2nd argument) occurrences of character in the 1st argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

c- Character

i- Count

`Returns:` text_t

`*SKIP` (`uint` i)

Select the Text after skipping over a prefix in the current Text. The length of the prefix is equal to the number in the argument. If there aren't enough characters in the Text object then the entire Text is skipped over.

`Parameters` (expressions not allowed) `:`

i- Prefix Length

`Returns:` text_t

`*STARTSWITH_ANY` (text_t patset_name)

Results in Boolean TRUE value if the Text starts with any of the strings that are bound to the patset or dataset named by the string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` bool_at

`*STARTSWITH_INDEX` (text_t patset_name)

Returns the numerical index of the matching string, if the Text starts with any of the strings that are bound to the patset or dataset named by the string argument. Returns 0 if there is no match. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` num_at

`*STARTSWITH` (text_t start)

Results in Boolean TRUE value if a prefix of the Text object matches the string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

start- String

`Returns:` bool_at

`*STRIP_CHARS` (text_t s)

From the selected text remove the characters specified in the string.

For example: Say the selected text is / "foo.xyz=bar" /. Then on executing STRIP_CHARS('.=') or STRIP_CHARS('..=') the selected text will become /fooxyzbar /. Note that repeating character has

same effect as it would be if it present only once. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*STRIP_END_CHARS` (text_t s)

Selects the Text after stripping off characters in the end of the current Text object.

For example: Say the selected text is / "foo.xyz=bar" /. Then on executing STRIP_END_CHARS('ar') the selected text will become /foo.xyz=b /. Note that repeating character has same effect as it would be if it present only once. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*STRIP_END_WS`

Selects the Text after stripping off white space in the end of the current Text object.

`Returns:` text_t

`*STRIP_START_CHARS` (text_t s)

Selects the Text after stripping off characters in the beginning of the current Text object.

For example: Say the selected text is / "foo.xyz=bar" /. Then on executing STRIP_START_CHARS('of') the selected text will become /.xyz=bar /. Note that repeating character has same effect as it would be if it present only once. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*STRIP_START_WS`

Selects the Text after stripping off white space in the beginning of the current Text object.

`Returns:` text_t

`*SUBSTR_ANY` (text_t patset_name)

Select any one sub-string that matches any string in the given patset or dataset. The patset cannot have strings longer than 255 characters. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` text_t

`*SUBSTR` (`uint` start, `uint` len)

Select the Text object of the given length at the given offset. Offset it 0 based. If there aren't enough characters after the offset then all the remaining characters are selected.

`Parameters``:`

start- Offset

len- Length

`Returns:` text_t

`*SUBSTR` (text_t s)

Select the first Text object that matches the input string argument. The input string cannot be bigger than 255 characters. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*SUFFIX` (`char` c, `uint` i)

Select a suffix of the Text. The selected suffix is the longest possible suffix containing at most Count (2nd arg) occurrences of the character in the 1st argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

c- Character

i- Count

`Returns:` text_t

`*SUFFIX` (`uint` i)

Select a suffix of the Text. The length of the suffix is equal to the number in the argument. If there aren't enough characters in the Text object then the entire Text is selected.

`Parameters``:`

i- Suffix Length

`Returns:` text_t

`*TO_LOWER`

Converts the selected text to lower case.

For example, the string "ABCd" is converted to "abcd"

`Returns:` text_t

`*TO_UPPER`

Converts the selected text to upper case.

For example, the string "abcD" is converted to "ABCD"

`Returns:` text_t

`*TRUNCATE` (`char` c, `uint` i)

Select the Text after truncating a suffix from the current Text object. The truncated suffix is the longest possible suffix containing at most Count (2nd arg) occurrences of the character in the 1st argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

c- Character

i- Count

`Returns:` text_t

`*TRUNCATE` (`uint` i)

Select the Text after truncating a suffix of the Text. The length of the suffix truncated is equal to the number in the argument. If there aren't enough characters in the Text then then all the characters are truncated.

`Parameters``:`

i- Suffix Length

`Returns:` text_t

`*TYPECAST_AVP_T`

Convert text_t to avp_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (avp_t : Operations that can be performed on the returned AVPs.

`Note:` An AVP can have multiple instances in a Diameter message. However, the system can access only the first 16 instances.

`Example:`

- To get the first value of AVP code 266 from a request, use: DIAMETER.REQ.AVP(266).VALUE(0).
- To get the fourth value of AVP code 266 from a request, use: DIAMETER.REQ.AVP(266).VALUE(3).
- To check if AVP code 1000 in the response has the vendor-specific bit set, use: DIAMETER.RES.AVP(1000).IS_VENDOR_SPECIFIC.

)

`Returns:` avp_t

`*TYPECAST_AVP_UNUM_T`

Convert text_t to avp_unum_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (avp_unum_t : In Diameter AVP based expressions can be written as DIAMETER.REQ.AVP(<avpcode>). For example Auth-Application-Id AVP (AVP code

258) can be extracted as DIAMETER.REQ.AVP(258) For few of the important AVPs we provide aliases. For example this AVP based expression can also be written as DIAMETER.REQ.AUTH_APPLICATION_ID. This expression returns either a object of class avp_t or returns a numerical value (object of class unsigned_long_at). The numerical value for this object is derived from the value in first instance of the AVP.)

`Returns:` avp_unum_t

`*TYPECAST_BOOL_AT`

Convert text_t to bool_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (bool_at : Boolean Operations)

`Returns:` bool_at

`*TYPECAST_COOKIE_T`

Convert text_t to cookie_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (cookie_t : The HTTP Cookie type provides operations for a cookie as it appears in the Set-Cookie and Set-Cookie2 header. In this type the Name-Value List operations are also available. The first delimiter is = and the element delimiter is ;. Multiple consecutive ; are treated as one. (Same as applying the method IGNORE_EMPTY_ELEMENTS on a Name-Value List.) You can use the Name-value List operations to access cookie attributes. The name comparison for all list operations is case insensitive. In this type Text operations are also available. Each cookie begins with a COOKIE_NAME=COOKIE_VALUE pair followed by zero or more semi-colon separated attribute-value pairs. If an attribute appears more than once in a cookie, the value associated with the first appearance of the attribute is returned.

Format Cookie: Cookie1=Value;Version=decimal;Value;Domain=Value;Path=Value)

`Returns:` cookie_t

`*TYPECAST_DIAMETER_FLAG_T`

Convert text_t to diameter_flag_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (diameter_flag_t : Provides operation to treat the underlying 1 byte as set of bit flags. then set/unset/test/reset_all operations can be done on flag)

`Returns:` diameter_flag_t

`*TYPECAST_DNS_DOMAINNAME_T`

Convert text_t to dns_domainname_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (dns_domainname_t : This object provides operations for parsing the DNS domain name as it appears at various places in the DNS data. The format is abc.foo.com.)

`Returns:` dns_domainname_t

`*TYPECAST_DNS_FLAG_T`

Convert text_t to dns_flag_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (dns_flag_t : Provides operations to test/set/unset a flag in dns header.)

`Returns:` dns_flag_t

`*TYPECAST_DOUBLE_AT`

Convert text_t to double_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_at : Double Value)

`Returns:` double_at

`*TYPECAST_DOUBLE_T` (double_format_e format)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error.)

`Parameters` (expressions not allowed) `:`

format- Format

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, double_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the

beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, ip_address_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, num_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, time_local_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, time_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, unsigned_long_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_HTTP_CACHE_CONTROL_T`

Convert text_t to http_cache_control_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_cache_control_t : This object provides for the ability to work on HTTP Cache-Control headers. The name comparison for all list operations is case insensitive.)

`Returns:` http_cache_control_t

`*TYPECAST_HTTP_CONTENT_LENGTH_T`

Convert text_t to http_content_length_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_content_length_t : The HTTP.REQ.CONTENT_LENGTH or HTTP.RES.CONTENT_LENGTH object can be treated as a HTTP Header or as a Number. The numerical value for this object is derived from the value in the last instance of the Content-Length header.)

`Returns:` http_content_length_t

`*TYPECAST_HTTP_COOKIE_T`

Convert text_t to http_cookie_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_cookie_t : This object provides operations for parsing the HTTP cookie header. The name-value pair is derived from the value in the last instance of Cookie header. The format is Cookie : name0=value0; name1=value1; An HTTP Cookie header can have multiple occurrences. COUNT will return a Number containing how many headers of the

current type exist. The name comparison for all list operations is case insensitive. The system does not keep track of more than 15 HTTP headers. The result will be undefined if there are more than 15 instances of the header.)

`Returns:` http_cookie_t

`*TYPECAST_HTTP_DATE_T`

Convert text_t to http_date_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_date_t : The HTTP.REQ.DATE or HTTP.RES.DATE object can be treated as a HTTP header or a Time object. The Time value is derived from the value in the last instance of the Date header. The date formats supported are RFC 822 (updated by RFC 1123), RFC 1036 (obsoletes RFC850) and ANSI C asctime() formats.)

`Returns:` http_date_t

`*TYPECAST_HTTP_HEADER_T` (text_t name)

Convert text_t to http_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_header_t : When typecasting a Text object to HTTP Header a header name must be provided.For example: HTTP.REQ.HEADER("MyHdr").TYPECAST_HTTP_HEADER_T("InHdr"))

`Parameters` (expressions not allowed) `:`

name- Header Name

`Returns:` http_header_t

`*TYPECAST_HTTP_HOSTNAME_T`

Convert text_t to http_hostname_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_hostname_t : This object provides operations for parsing the HTTP hostname as it appears at various places in the HTTP protocol data. The format is abc.foo.com:8080.)

`Returns:` http_hostname_t

`*TYPECAST_HTTP_METHOD_T`

Convert text_t to http_method_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_method_t : This object provides Text operations and HTTP Request Method Enum operations on the HTTP request method.)

`Returns:` http_method_t

`*TYPECAST_HTTP_SET_COOKIE_T`

Convert text_t to http_set_cookie_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_set_cookie_t : HTTP.RES.SET_COOKIE provides operations for parsing and operating on the SET-COOKIE header that is present in the HTTP response. HTTP Set-Cookie header supports Text and HTTP Header operations. For most Text operations the value in the last Set-Cookie header is selected. HTTP Set-Cookie header also supports special operations to extract cookies from the response. It is assumed that there will be only one cookie in a Set-Cookie header.)

`Returns:` http_set_cookie_t

`*TYPECAST_HTTP_URL_T`

Convert text_t to http_url_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_url_t : HTTP.REQ.URL provides operations for parsing and operating on the URL that is present in the first line of the HTTP request header. The supported format is \[<protocol>://<hostname>\]<path>?<query>. The Text object backing a HTTP URL object has the Text Mode set to URLENCODED by default.)

`Returns:` http_url_t

`*TYPECAST_HTTP_VERSION_T`

Convert text_t to http_version_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_version_t : HTTP.REQ.VERSION or HTTP.RES.VERSION provide operations to extract HTTP version information.)

`Returns:` http_version_t

`*TYPECAST_IPV6_ADDRESS_AT`

Convert text_t to ipv6_address_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ipv6_address_at : Provides operations for the 128-bit IPv6 address value. Some general information regarding IPv6 expressions: IPv6 PIXL expressions can be combined with other PIXL expressions using the '+' operator. The output is expected to be the concatenation of the string representations of the individual PIXL expressions. No other operator other than '+' is expected to work when any of the operands is an IPv6 PIXL expression. Also, IPv6 PIXL expressions can be combined with any other type of PIXL expression except a PIXL expression that produces a bool result. In other words, if A and/or B are two IPv6 addresses,

A+B should result in the string AB. When one of A or B is an IPv6 address, the other can only be a number or a string and not a boolean. Further, when A and/or B is an IPv6 address, the only operator allowed between them is '+'.

Example: Let the client source IPv6 address be ABCD:1234::ABCD. Let the server destination IPv4 address be 10.100.10.100. Then the expression CLIENT.IPV6.SRC + SERVER.IP.DST should produce the output "ABCD:1234::ABCD10.100.10.100". Similarly, CLIENT.IPV6.SRC + 5 should produce the result ABCD:1234::ABCD5)

`Returns:` ipv6_address_at

`*TYPECAST_IPV6_ADDRESS_T`

Convert text_t to ipv6_address_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ipv6_address_t : This object represents an IPv6 address present in the 1000:1001:CD10:0000:0000:89AB:4567:CDEF format.)

`Returns:` ipv6_address_t

`*TYPECAST_IPV6_SUBNET_AT`

Convert text_t to ipv6_subnet_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ipv6_subnet_at : Provides operations for the integral IPv6 subnet address value.)

`Returns:` ipv6_subnet_at

`*TYPECAST_IPV6_SUBNET_T`

Convert text_t to ipv6_subnet_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ipv6_subnet_t : This object represents an IPv6 subnet address present in the 1000:1001:CD10:0000:0000:89AB:4567:CDEF/64 format.)

`Returns:` ipv6_subnet_t

`*TYPECAST_IP_ADDRESS_AT`

Convert text_t to ip_address_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ip_address_at : Provides operations for the 32-bit integral IP address value.)

`Returns:` ip_address_at

`*TYPECAST_IP_ADDRESS_T`

Convert text_t to ip_address_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ip_address_t : Represents an IP address present in the 10.100.200.1 format.)

`Returns:` ip_address_t

`*TYPECAST_IP_OPTIONS_T`

Convert text_t to ip_options_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ip_options_t : IP protocol options)

`Returns:` ip_options_t

`*TYPECAST_IP_OPTIONS_TYPE_T`

Convert text_t to ip_options_type_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ip_options_type_t : IP Options Type)

`Returns:` ip_options_type_t

`*TYPECAST_IP_TOS_T`

Convert text_t to ip_tos_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ip_tos_t : Provides operations to TOS field in IP header.)

`Returns:` ip_tos_t

`*TYPECAST_LIST_T` (`char` sep)

Convert text_t to list_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (list_t : The character separator has to be provided when typecasting a textual context to list type. The current text mode has no effect on the character separator. For example if the current text mode is IGNORECASE and the separator is p then P will not be treated as a separator.)

`Parameters` (expressions not allowed) `:`

sep- Separator

`Returns:` list_t

`*TYPECAST_MAC_ADDRESS_AT`

Convert text_t to mac_address_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (mac_address_at : Provides operations for the 48-bit MAC address value.)

`Returns:` mac_address_at

`*TYPECAST_MAC_ADDRESS_T`

Convert text_t to mac_address_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (mac_address_t : Represents a MAC address present in the 12:34:56:78:9a:bc format.)

`Returns:` mac_address_t

`*TYPECAST_NUM_AT`

Convert text_t to num_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (num_at : Number Value)

`Returns:` num_at

`*TYPECAST_NUM_T` (num_format_e format)

Convert text_t to num_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (num_t : Treat the underlying text as a Number in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error.)

`Parameters` (expressions not allowed) `:`

format- Format

`Returns:` num_t

`*TYPECAST_NUM_T` (num_format_e format, num_at default_value)

Convert text_t to num_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (num_t : Treat the underlying text as a Number in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL

and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` num_t

`*TYPECAST_NVLIST_T` (`char` sep1, `char` sep2)

Convert text_t to nvlist_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (nvlist_t : Two character delimiters have to be provided when typecasting a Text object to a Name-Value List. The first delimited separates the name from the value. The second delimiter separates list items. For example typecast_nvlist_t('=', '&') handles a URL query string. The Text Mode has no effect on the character delimiters. For example if the current text mode is IGNORECASE and a delimiter is p then P will not be treated as a delimiter.)

`Parameters` (expressions not allowed) `:`

sep1- delimiter1

sep2- delimiter2

`Returns:` nvlist_t

`*TYPECAST_NVLIST_T` (`char` sep1, `char` sep2, `char` quote)

Convert text_t to nvlist_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (nvlist_t : Two character delimiters and quote-character have to be provided when typecasting a Text object to a Name-Value List that supports quote-character. The first delimited separates the name from the value. The second delimiter separates list items. The third value specifies the quote character. For example typecast_nvlist_t('=', ';', "") handles a name-value list separated by semi-colons that allows quoting. The quote-character specifies that the value can occur within the quotes and the delimiters within the quote-characters should not be taken into account. The Text Mode has no effect on the character delimiters. For example if the current text mode is IGNORECASE and a delimiter is p then P will not be treated as a delimiter.)

`Parameters` (expressions not allowed) `:`

sep1- delimiter1

sep2- delimiter2

quote- quote-character.

`Returns:` nvlist_t

`*TYPECAST_PROTOCOL_BUFFER_T`

Convert text_t to protocol_buffer_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (protocol_buffer_t : gRPC Protocol Buffers interface)

`Returns:` protocol_buffer_t

`*TYPECAST_RADIUS_AVP_T`

Convert text_t to radius_avp_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (radius_avp_t : Operations that can be performed on the returned AVPs.

`Note:` An AVP can have multiple instances in a radius message. However, the system can access only the first 16 instances.

`Example:`

- To get the first value of AVP code 26 from a request, use: radius.REQ.AVP(26).VALUE(0).
- To get the fourth value of AVP code 26 from a request, use: radius.REQ.AVP(26).VALUE(3).

)

`Returns:` radius_avp_t

`*TYPECAST_RADIUS_AVP_VALUE_T`

Convert text_t to radius_avp_value_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (radius_avp_value_t : Provides operations to typecast RADIUS AVP value to Integer value or IP Address.)

`Returns:` radius_avp_value_t

`*TYPECAST_SEQ_TEXT_T`

Convert text_t to seq_text_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (seq_text_t : Represents the Text Sequence class.)

`Returns:` seq_text_t

`*TYPECAST_SERVICEPATH_T`

Convert text_t to servicepath_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (servicepath_t : Operations that can be performed on the service path.

`Example:`

- To get the name of the service path applicable to current subscriber, use: SUBSCRIBER.SERVICEPATH
- To determine If the service function is the next in the service path applicable to scubscriber, use: SUBSCRIBER.SERVICEPATH.IS_NEXT().

)

`Returns:` servicepath_t

`*TYPECAST_SIP_CALLID_HEADER_T`

Convert text_t to sip_callid_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_callid_header_t : This object provides operations for parsing the SIP callid header.)

`Returns:` sip_callid_header_t

`*TYPECAST_SIP_CONTENT_LENGTH_T`

Convert text_t to sip_content_length_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_content_length_t : The SIP.REQ.CONTENT_LENGTH or SIP.RES.CONTENT_LENGTH object can be treated as a SIP Header or as a Number. The numerical value for this object is derived from the value in the last instance of the Content-Length header.)

`Returns:` sip_content_length_t

`*TYPECAST_SIP_FROM_HEADER_T`

Convert text_t to sip_from_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_from_header_t : This object provides operations for parsing the SIP From header.)

`Returns:` sip_from_header_t

`*TYPECAST_SIP_HEADER_T` (text_t name)

Convert text_t to sip_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_header_t : When typecasting a Text object to SIP Header a header name must be provided.For example: SIP.REQ.HEADER("MyHdr").TYPECAST_SIP_HEADER_T("InHdr"))

`Parameters` (expressions not allowed) `:`

name- Header Name

`Returns:` sip_header_t

`*TYPECAST_SIP_HOSTNAME_T`

Convert text_t to sip_hostname_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_hostname_t : This object provides operations for parsing the SIP hostname as it appears at various places in the SIP protocol data. The format is abc.foo.com:5060.)

`Returns:` sip_hostname_t

`*TYPECAST_SIP_METHOD_T`

Convert text_t to sip_method_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_method_t : This object provides Text operations and SIP Request Method Enum operations on the SIP request method.)

`Returns:` sip_method_t

`*TYPECAST_SIP_TO_HEADER_T`

Convert text_t to sip_to_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_to_header_t : This object provides operations for parsing the SIP From header.)

`Returns:` sip_to_header_t

`*TYPECAST_SIP_URL_T`

Convert text_t to sip_url_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_url_t : SIP.REQ.URL provides operations for parsing and operating on the URL that is present in the first line of the SIP request header. The supported format is \[<protocol>://<hostname>\]<path>?<query>. The Text object backing a SIP URL object has the Text Mode set to URLENCODED by default.)

`Returns:` sip_url_t

`*TYPECAST_SIP_VERSION_T`

Convert text_t to sip_version_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_version_t : SIP.REQ.VERSION or SIP.RES.VERSION provide operations to extract SIP version information.)

`Returns:` sip_version_t

`*TYPECAST_SIP_VIA_HEADER_T`

Convert text_t to sip_via_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_via_header_t : This object provides operations for parsing the SIP Via header.)

`Returns:` sip_via_header_t

`*TYPECAST_SSLVPN_MODE_T`

Convert text_t to sslvpn_mode_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sslvpn_mode_t : This object provides Text operations and SSLVPN Mode Enum operations on the SSLVPN request method.)

`Returns:` sslvpn_mode_t

`*TYPECAST_SSL_TEXT_T` (text_t name)

Convert text_t to ssl_text_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ssl_text_t : Treat the underlying text object as SSL Text.)

`Parameters` (expressions not allowed) `:`

name- Name

`Returns:` ssl_text_t

`*TYPECAST_TCP_OPTIONS_T`

Convert text_t to tcp_options_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (tcp_options_t : TCP Protocol Options)

`Returns:` tcp_options_t

`*TYPECAST_TCP_OPTIONS_TYPE_T`

Convert text_t to tcp_options_type_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (tcp_options_type_t : TCP Protocol Options Type)

`Returns:` tcp_options_type_t

`*TYPECAST_TCP_REPEATER_OPTION_T`

Convert text_t to tcp_repeater_option_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (tcp_repeater_option_t : TCP Protocol Option : Repeater)

`Returns:` tcp_repeater_option_t

`*TYPECAST_TIME_AT`

Convert text_t to time_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (time_at : Treats a number value as number of seconds since GMT Jan 1 1970 0h 0m 0s.)

`Returns:` time_at

`*TYPECAST_TIME_LOCAL_AT`

Convert text_t to time_local_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (time_local_at : Treats a number value as number of seconds since GMT Jan 1 1970 0h 0m 0s as adjsuted for the local time zone.)

`Returns:` time_local_at

`*TYPECAST_TIME_T`

Convert text_t to time_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (time_t : This object treats a Text object as a date string. The formats supported are

1\. RFC822 :: Sun, 06 Nov 1994 08:49:37 GMT 2\. RFC850 :: Sunday, 06-Nov-94 08:49:37 GMT 3\. ASCTIME :: Sun Nov 6 08:49:37 1994 4\. ASCTIME like :: Sun Nov 6 08:49:37 1994 5\. ASCTIME like :: Sun Nov 06 08:49:37 1994 6\. Http Set-Cookie Expiry date :: Sun, 06-Nov-1994 08:49:37 GMT)

`Returns:` time_t

`*TYPECAST_UNSIGNED_LONG_AT`

Convert text_t to unsigned_long_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_at : Unsigned Long(64bit) Value)

`Returns:` unsigned_long_at

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error.)

`Parameters` (expressions not allowed) `:`

format- Format

`Returns:` unsigned_long_t

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format, ip_address_at default_value)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` unsigned_long_t

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format, unsigned_long_at default_value)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` unsigned_long_t

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format, num_at default_value)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` unsigned_long_t

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format, time_local_at default_value)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` unsigned_long_t

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format, time_at default_value)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` unsigned_long_t

`*TYPECAST_UNUM_TEXT_T`

Convert text_t to unum_text_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unum_text_t : Provides operations to treat the underlying OctectString as Binary String or unsigned long value .)

`Returns:` unum_text_t

`*TYPECAST_URL_CATEGORY_T`

Convert text_t to url_category_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (url_category_t : Retrieves URL category and attributes from an URL)

`Returns:` url_category_t

`*TYPECAST_VENDOR_SPEC_APPID_AVP_T`

Convert text_t to vendor_spec_appid_avp_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (vendor_spec_appid_avp_t : Retrieves AVPs that are nested in the grouped AVP Vendor-Specific-Application-Id (code 260). The nested AVPs are:

- Vendor-Id
- Auth-Application-Id
- Acct-Application-Id

For example, to retrieve the Auth-Application-Id AVP from the Vendor-Specific-Application-Id AVP:

- For requests: DIAMETER.REQ.VENDOR_SPECIFIC_APPLICATION_ID.AUTH_APPLICATION_ID
- For responses: DIAMETER.RES.VENDOR_SPECIFIC_APPLICATION_ID.AUTH_APPLICATION_ID

)

`Returns:` vendor_spec_appid_avp_t

`*TYPECAST_VENDOR_SPEC_RADIUS_AVP_T`

Convert text_t to vendor_spec_radius_avp_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (vendor_spec_radius_avp_t :

- Vendor-Id

To retrieve the Vendor-Id from the Vendor-Specific AVP:

- RADIUS.REQ.VENDOR_SPECIFIC.VENDORID

)

`Returns:` vendor_spec_radius_avp_t

`*UNQUOTE` (`char` c)

If selected text is quoted by character c, Remove character c from beginning and end.

For example: Say the selected text is / "foo xyz bar " /. Then on executing UNQUOTE("") the selected text will become /foo xyz bar / This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

c- Character

`Returns:` text_t

`*URLSET_MATCHES_ANY` (text_t urlset_name)

Results in Boolean TRUE value if and only if the Text matches any of the patterns that are specified in the urlset named by the string argument. The matching is case-insensitive for domains, but case-sensitive for paths. For example:

- HTTP.REQ.HOST.APPEND(HTTP.REQ.URL).URLSET_MATCHES_ANY("urlset_forbidden") returns true when the combined domain and URL matches any pattern in the urlset whose name is "urlset_forbidden".

`Parameters` (expressions not allowed) `:`

urlset_name- urlset name

`Returns:` bool_at

`*URL_CATEGORIZE` (`uint` min_reputation, `uint` max_reputation)

Returns the URL category for the supplied URL with the given minimum and maximum reputation score. Where a score of 5 is most risky and 1 is least risky. If either score is set to 0, that bound would be ignored. By specifying the reputation scores, the function will returned the category with the highest score (most risky) based on the bounds. If there was an error getting the category or if the URL is invalid then it will result in an Undef error. For example:

HTTP.REQ.HOST.APPEND(HTTP.REQ.URL).URL_CATEGORIZE(0, 0) returns value when the combined domain and URL is looked up for the URL category with the highest reputation score (most risky).

`Parameters` (expressions not allowed) `:`

min_reputation- Minimum reputation score of URL category

max_reputation- Maximum reputation score of URL category

`Returns:` url_category_t

`*URL_RESERVED_CHARS_SAFE`

Converts URL reserved characters to corresponding '%XX' values and retains the rest. This is a read only operation.

```
Based on RFC3986, following are considered URL unreserved characters:

    Alpha-numeric characters: a-z, A-Z, 0-9

    Hyphen and underscore: "-", "_"

    Dot: "."

    Tilde: "~"
```

The rest are converted to %XX encoding, 'XX' is the hex-based representation of the input character. If the requirement is to encode all but URL safe characters, please consider using HTTP_URL_SAFE method.

`Returns:` text_t

`*XML_DECRYPT` (text_t certKeyName)

Decrypt the selected content, which was encrypted using the W3C XML Encryption standard.

`Parameters` (expressions not allowed) `:`

certKeyName- identifies the certkey object containing the RSA private key to be used to decrypt the bulk encryption key in the selected EncryptedData element.

`Returns:` text_t

`*XML_ENCRYPT` (text_t certKeyName, encrypt_method_e method)

Encrypt the selected cleartext using the W3C XML Encryption standard.

`Parameters` (expressions not allowed) `:`

certKeyName- identifies the certkey object containing an X.509 certificate with the RSA public key to be used to encrypt the generated bulk encryption key. Note that the certKey object need not, and usually will not, include the associated RSA private key.

method- specifies the bulk encryption method (rc4, des3, aes128, aes192, or aes256) used to encrypt the content.

`Returns:` text_t

`*XML_ENCRYPT` (text_t certKeyName, encrypt_method_e method, `uint` flags)

Encrypt the selected cleartext using the W3C XML Encryption standard.

`Parameters` (expressions not allowed) `:`

certKeyName- identifies the certkey object containing an X.509 certificate with the RSA public key to be used to encrypt the generated bulk encryption key. Note that the certKey object need not, and usually will not, include the associated RSA private key.

method- specifies the bulk encryption method (rc4, des3, aes128, aes192, or aes256) used to encrypt the content.

flags- optional bit mask to specify optional elements in the EncryptedData element. These are hints to tell the receiver what private key to use to decrypt the bulk encryption key, providing information from the certKey's X.509 certificate.

- 1 - include a KeyName element with the certKeyName;
- 2 - include a KeyValue element with the RSA public key from the certificate;
- 4 - include an X509IssuerSerial element with the certificate serial number and issuer DN;
- 8 - include an X509SubjectName element with the certificate subject DN;
- 16 - include an X509Certificate element with the entire certificate;

`Returns:` text_t

`*XPATH_HTML_WITH_MARKUP` (`xpath_str` xpathex)

Applies an XPath expression to the DOM for an HTML document and returns the selected node-set or string, including markup like element tags. node-sets are converted to strings using the standard XPath string conversion routine. The selected portion of the document can be used as the target for rewrite actions.

Examples: HTTP.REQ.BODY(1000).XPATH_HTML_WITH_MARKUP(xp%//md/head/title%) returns the <title> element in the document's <head> This can be used in a rewrite action to replace or delete the <title> element.

`Parameters` (expressions not allowed) `:`

xpathex- XPath Expression

`Returns:` text_t

`*XPATH_HTML` (`xpath_bool` xpathex)

Applies an XPath expression to the DOM for an HTML document and a boolean value.

Examples: HTTP.RES.BODY(1000).XPATH_HTML(xp%boolean(/md/head/meta)%) returns true if the <meta> element exists as a child of <head> element.

`Parameters` (expressions not allowed) `:`

xpathex- XPath Expression

`Returns:` bool_at

`*XPATH_HTML` (`xpath_double` xpathex)

Applies an XPath expression to the DOM for an HTML document and a double value.

Examples: HTTP.RES.BODY(1000).XPATH_HTML(xp%number(//video/@height)%) returns the numeric value of the height attribute of the first <video> element.

`Parameters` (expressions not allowed) `:`

xpathex- XPath Expression

`Returns:` double_at

`*XPATH_HTML` (`xpath_str` xpathex)

Applies an XPath expression to the DOM for an HTML document and returns the selected node-set or string. node-sets are converted to strings using the standard XPath string conversion routine.

Examples: HTTP.REQ.BODY(1000).XPATH_HTML(xp%//img/@src%) returns the string value of the src attribute of the first

```

HTTP_PROTOCOL_T

Models the HTTP message types.

This topic lists the expressions that are provided by this class.

- `REQ`

  Operates on HTTP Request.

`Returns:` http_req_t

- `RES`

  Operates on HTTP Response.

`Returns:` http_res_t

HTTP_REQ_T

Operates on HTTP Request.

This topic lists the expressions that are provided by this class.

`BODY` (`uint` i)

Operate as Text on the HTTP response body. The length of the body is equal to the number in the argument. If there aren't enough characters in the body then the entire body is selected.

`Parameters``:`

i- Body length

`Returns:` text_t

- `CACHE_CONTROL`

  Returns the HTTP Cache-Control object.

`Returns:` http_cache_control_t

- `CONTENT_LENGTH`

  Returns the length of the HTTP request as a number.

`Returns:` http_content_length_t

- `COOKIE`

  (Name/Value List) Returns the contents of the HTTP Cookie header as a name/value list.

`Returns:` http_cookie_t

- `CS_VSERVER`

  Returns the CS vserver serving the current request.

`Returns:` vserver_t

- `DATE`

Returns the contents of the HTTP Date header as text or as a date object.The date formats recognized are: RFC822. Sun, 06 Jan 1980 08:49:37 GMT RFC850. Sunday, 06-Jan-80 9:49:37 GMT ASCTIME. Sun Jan 6 08:49:37 1980

`Returns:` http_date_t

- `FULL_HEADER`

  Returns the entire request header (including the terminating \\r\\n\\r\\n)

`Returns:` text_t

`HEADER` (text_t header_name)

Returns the contents of the HTTP header specified by the String argument. The header name cannot be longer than 32 characters.

`Parameters` (expressions not allowed)`:`

header_name- Header Name

`Returns:` http_header_t

- `HOSTNAME`

  Obtain the HTTP Host Name object from this request. If the target hostname is present in the first line of the request then that is selected. Otherwise the value in the last occurrence of the HOST header is selected. Sets the text mode to case insensitive.

`Returns:` http_hostname_t

- `IS_NTLM_OR_NEGOTIATE`

  Returns TRUE if request is part of NTLM or NEGOTIATE connection

`Returns:` bool_at

- `IS_VALID`

  Returns TRUE if the HTTP request is properly formed.

`Returns:` bool_at

- `LB_VSERVER`

  Returns the LB vserver serving the current request.

`Returns:` vserver_t

- `METHOD`

  Returns the HTTP method.

`Returns:` http_method_t

- `TRACKING`

  Returns the HTTP body tracking mechanism.

`Returns:` http_tracking_e

- `TXID`

  Returns the HTTP Transaction ID. The value is a function of an internal transaction number, system boot time and system mac address. HTTP.REQ.TXID is same as HTTP.RES.TXID.

`Returns:` text_t

- `URL`

  Obtain the HTTP URL object from the request. The Text object backing the HTTP URL object has the Text Mode set to URLENCODED by default.

`Returns:` http_url_t

- `USER`

  Returns the AAA User associated with the current HTTP transaction.

`Returns:` aaa_user_t

- `VERSION`

  Returns the HTTP version.

`Returns:` http_version_t

HTTP_RES_T

Operates HTTP Response.

This topic lists the expressions that are provided by this class.

`BODY` (`uint` i)

Operate as Text on the HTTP response body. The length of the body is equal to the number in the argument. If there aren't enough characters in the body then the entire body is selected.

`Parameters``:`

i- Body length

`Returns:` text_t

- `CACHE_CONTROL`

  Returns the HTTP Cache-Control object

`Returns:` http_cache_control_t

- `CONTENT_LENGTH`

  Returns the length of the HTTP response as a number.

`Returns:` http_content_length_t

- `DATE`

  Returns the contents of the HTTP Date header as text or as a date object.The date formats recognized are: RFC822. Sun, 06 Jan 1980 08:49:37 GMT RFC850. Sunday, 06-Jan-80 9:49:37 GMT ASCTIME. Sun Jan 6 08:49:37 1980

`Returns:` http_date_t

- `FULL_HEADER`

  Returns the entire response header (including the terminating \\r\\n\\r\\n)

`Returns:` text_t

`HEADER` (text_t header_name)

Returns the contents of the HTTP headerspecified by the String argument. The header name cannot be longer than 32 characters.

`Parameters` (expressions not allowed) `:`

header_name- Header Name

`Returns:` http_header_t

- `IS_CLIENT_ERROR`

  Returns True if response code is 4xx.

`Returns:` bool_at

- `IS_INFORMATIONAL`

  Returns True if response code is 1xx.

`Returns:` bool_at

- `IS_REDIRECT`

  Returns True if response code is 3xx.

`Returns:` bool_at

- `IS_SERVER_ERROR`

  Returns True if response code is 5xx.

`Returns:` bool_at

- `IS_SUCCESSFUL`

  Returns True if response code is 2xx.

`Returns:` bool_at

- `IS_VALID`

  Returns TRUE if the HTTP request is properly formed.

`Returns:` bool_at

- `MEDIA`

  Designates an expression that refers to media analytics

`Returns:` media_t

- `SET_COOKIE`

  Obtain the HTTP Set-Cookie Header Object from this response.

`Returns:` http_set_cookie_t

- `SET_COOKIE2`

  Obtain the HTTP Set-Cookie2 Header Object from this response.

`Returns:` http_set_cookie_t

- `STATUS`

  Returns the HTTP response status code.

`Returns:` num_t

- `STATUS_MSG`

  Returns the HTTP response status message.

`Returns:` text_t

- `TRACKING`

  Returns the HTTP body tracking mechanism.

`Returns:` http_tracking_e

- `TXID`

  Returns the HTTP Transaction ID. The value is a function of an internal transaction number, system boot time and system mac address. HTTP.REQ.TXID is same as HTTP.RES.TXID.

`Returns:` text_t

- `VERSION`

Returns the HTTP version.

`Returns:` http_version_t

HTTP_SET_COOKIE_T

HTTP.RES.SET_COOKIE provides operations for parsing and operating on the SET-COOKIE header that is present in the HTTP response. HTTP Set-Cookie header supports Text and HTTP Header operations. For most Text operations the value in the last Set-Cookie header is selected. HTTP Set-Cookie header also supports special operations to extract cookies from the response. It is assumed that there will be only one cookie in a Set-Cookie header.

This topic lists the expressions that are provided by this class.

`*Note` *: Expressions with the * symbol are inherited / promoted from http_header_t

`COOKIE` (text_t name)

Returns the Cookie with Cookie_name if present else NULL (Text of length 0 pointing nowhere) is returned. The name comparison is case insensitive. Raises UNDEF if more than 15 Set-Cookie headers are present and the Cookie could not be found in the first 15 headers.

`Parameters` (expressions not allowed) `:`

name- Cookie_Name

`Returns:` cookie_t

`*COOKIE` (text_t name, `uint` i)

Returns the i-th instance of Cookie with name if present else NULL (Text with length 0 pointing nowhere) is returned. The index of the Cookie component given by the argument is 0-based. The name comparison is case insensitive. Raises UNDEF if more than 15 Set-Cookie headers are present and the Cookie could not be found in the first 15 headers.

`Parameters` (expressions not allowed) `:`

name- Cookie_Name

i- Index

`Returns:` cookie_t

`*EXISTS` (text_t name)

Returns TRUE if the Cookie with name exists in the Set-Cookie header else FALSE. The name comparison is case insensitive. Raises UNDEF if more than 15 Set-Cookie headers are present and the Cookie could not be found in the first 15 headers.

`Parameters` (expressions not allowed) `:`

name- Cookie_Name

`Returns:` bool_at

`*TYPECAST_HTTP_HEADER_T`

Convert http_set_cookie_t to http_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_header_t : Typecast an HTTP Header object of a specific type to HTTP Header.For example: HTTP.REQ.CONTENT_LENGTH.TYPECAST_HTTP_HEADER_T)

`Returns:` http_header_t

`*AFTER_REGEX` (`re` regex)

The AFTER_REGEX operator in this object overrides the Text AFTER_REGEX operator to operate on all the instances of the current header type. Selects the Text after the text that matches the input regular expression in any instance of the header value. The order in which the header instances will be matched is from the last to the first.

For example: HTTP.REQ.HEADER("etag").AFTER_REGEX(re/KX/) will select "DAPPER" from "KXDAPPER". This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

regex- Regular Expression

`Returns:` text_t

`*AFTER_STR_ANY` (text_t patset_name)

Selects the Text that is present after the first occurrence of any of the strings that are bound to the patset named by the string argument. If there is no match to any of the strings bound to the patset in the current Text object then the result Text object has 0 length. The patset cannot have strings longer than 255 characters. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` text_t

`*AFTER_STR` (text_t s)

The AFTER_STR operator in this object overrides the Text AFTER_STR operator to operate on all the instances of the current header type. Selects Text after the first occurrence of the input string argument. The order in which the instances of the header are matched is from the last instance to the first.

HTTP/1.1 200 OK\\r\\n MyHdr: 111abc\\r\\n Content-Length: 200\\r\\n MyHdr: 111def\\r\\n \\r\\n

Examples: HTTP.RES.HEADER("MyHdr").AFTER_STR("111") selects "def" in the last instance of MyHdr, the one with value "111def". HTTP.RES.HEADER("MyHdr").AFTER_STR("1ab") selects "c" in the first instance of MyHdr, the one with value "abc111". This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*APPEND` (bool_at b)

Appends the given boolean's string representation to the current string.

`Parameters``:`

b- the boolean value to append.

`Returns:` text_t

`*APPEND` (double_at i)

Appends the given double's string representation to the current string.

`Parameters``:`

i- the double value to append.

`Returns:` text_t

`*APPEND` (ip_address_at addr)

Appends the given IPv4's string representation to the current string.

`Parameters``:`

addr- the IPv4 address to append.

`Returns:` text_t

`*APPEND` (num_at i)

Appends the given number's string representation to the current string.

`Parameters``:`

i- the number value to append.

`Returns:` text_t

`*APPEND` (time_local_at t)

Appends the given time's string representation to the current string.

`Parameters``:`

t- the time value to append.

`Returns:` text_t

`*APPEND` (time_at t)

Appends the given time's string representation to the current string.

`Parameters``:`

t- the time value to append.

`Returns:` text_t

`*APPEND` (unsigned_long_at i)

Appends the given unsigned long's string representation to the current string.

`Parameters``:`

i- the unsigned long value to append.

`Returns:` text_t

`*APPEND` (ipv6_address_at addr)

Appends the given IPv6's string representation to the current string.

`Parameters``:`

addr- the IPv6 address to append.

`Returns:` text_t

`*APPEND` (ipv6_subnet_at addr)

Appends the given IPv6 subnet's string representation to the current string.

`Parameters``:`

addr- the IPv6 subnet to append.

`Returns:` text_t

`*APPEND` (mac_address_at addr)

Appends the given MAC's string representation to the current string.

`Parameters``:`

addr- the MAC address to append.

`Returns:` text_t

`*APPEND` (text_t str)

Appends the given string to the current string.

`Parameters``:`

str- the string to append.

`Returns:` text_t

`*APPEND` (time_at t)

Appends the given time's string representation to the current string.

`Parameters``:`

t- the time value to append.

`Returns:` text_t

`*B64DECODE`

Decodes the selected text using base64 decoding.

For example, the string "TWFu" is converted to "Man"

`Returns:` text_t

`*B64ENCODE`

Encodes the selected text using base64 encoding.

For example, the string "Man" is converted to "TWFu"

`Returns:` text_t

`*BEFORE_REGEX` (`re` regex)

The BEFORE_REGEX operator in this object overrides the Text BEFORE_REGEX operator to operate on all the instances of the current header type. Selects the Text before the text that matches the input regular expression in any instance of the header value. The order in which the header instances will be matched is from the last to the first.

For example: HTTP.RES.HEADER("content-type").BEFORE_REGEX(re#/#) will select "text" from "text/plain". This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

regex- Regular Expression

`Returns:` text_t

`*BEFORE_STR_ANY` (text_t patset_name)

Selects the Text that is present before the first occurrence of any of the strings that are bound to the patset or datasetnamed by the string argument. If there is no match to any of the strings bound to the patset in the current Text object then the result Text object has 0 length. The patset cannot have strings longer than 255 characters. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` text_t

`*BEFORE_STR` (text_t s)

The BEFORE_STR operator in this object overrides the Text BEFORE_STR operator to operate on all the instances of the current header type. Selects Text before the first occurrence of the input string argument. The order in which the instances of the header are matched is from the last instance to the first.

HTTP/1.1 200 OK\\r\\n MyHdr: abc111\\r\\n Content-Length: 200\\r\\n MyHdr: def111\\r\\n \\r\\n

Examples: HTTP.RES.HEADER("MyHdr").BEFORE_STR("111") selects "def" in the last instance of MyHdr, the one with value "def111". HTTP.RES.HEADER("MyHdr").BEFORE_STR("bc1") selects "a" in the first instance of MyHdr, the one with value "abc111". This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*BETWEEN` (text_t start, text_t end)

Results in Boolean TRUE value if length of the Text object is greater than or equal to the sum of the Start and End argument lengths and if the prefix of the Text object matches the Start string argument and if the Suffix of the Text object matches the End string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

start- Start

end- End

`Returns:` bool_at

`*BIN_DECODE` (binary_encoding_e encoding)

Decode the encoded input into its original byte sequence. An incorrectly enooded input will result in an Undef error.

`Parameters` (expressions not allowed) `:`

encoding- specifies how the bytes are encoded.

`Returns:` text_t

`*BIN_ENCODE` (binary_encoding_e encoding)

Encode the input byte sequence. Note that BIN_ENCODE(hex_colons) is equivalent to BLOB_TO_HEX().

`Parameters` (expressions not allowed) `:`

encoding- specifies how the bytes are to be encoded.

`Returns:` text_t

`*BLOB_TO_HEX`

Convert to hexadecimal representation and select text.

For example, the byte string abc is converted to 61:62:63.

`Returns:` text_t

`*COMPARE` (text_t s)

Results in a Number Value which is the result of comparison of the input argument with the Text object. The result is greater than 0 if the Text object is lexicographically greater than the argument. The result is 0 if the Text object and the argument match. The result is less than 0 if the Text object is lexicographically lesser than the argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` num_at

`*CONTAINS_ANY` (text_t patclass_name)

The CONTAINS_ANY in this object overrides the Text CONTAINS_ANY operator to operate on all the instances of the current header type. Returns Boolean TRUE if any of the patterns associated with input patclass is present in any instance of the header value. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patclass_name- Patclass Name

`Returns:` bool_at

`*CONTAINS_INDEX` (text_t patclass_name)

The CONTAINS_INDEX in this object overrides the Text CONTAINS_INDEX operator to operate on all the instances of the current header type. Returns the index of the matching pattern associated with input patclass that is present in any instance of the header value. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed)`:`

patclass_name- Patclass Name

`Returns:` num_at

`*CONTAINS` (text_t s)

The CONTAINS in this object overrides the Text CONTAINS operator to operate on all the instances of the current header type. Returns Boolean TRUE if the input Pattern String is present in any instance of the header value.

GET / HTTP/1.1\\r\\n Host: abc.com\\r\\n MyHdr: abc\\r\\n Content-Length: 200\\r\\n MyHdr: def\\r\\n

HTTP/1.1 200 OK\\r\\n MyHdr: abc\\r\\n Content-Length: 200\\r\\n MyHdr: def\\r\\n \\r\\n

Examples: HTTP.RES.HEADER("MyHdr").CONTAINS("de") is TRUE.
HTTP.RES.HEADER("MyHdr").CONTAINS("bcd") is FALSE.
HTTP.REQ.HEADER("MyHdr").CONTAINS("de") is TRUE.
HTTP.REQ.HEADER("MyHdr").CONTAINS("bcd") is FALSE. The system does not concatenate the different values. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- Pattern String

`Returns:` bool_at

`*COUNT`

An HTTP header can have multiple occurrences. COUNT will return a Number containing how many headers of the current type exist.

HTTP/1.1 200 OK\\r\\n MyHdr: abc\\r\\n Content-Length: 200\\r\\n MyHdr: def\\r\\n \\r\\n

For example: HTTP.RES.HEADER("MyHdr").COUNT will return Number 2. The system does not keep track of more than 15 HTTP headers. The result will be undefined if there are more than 15 instances of the header.

`Returns:` num_at

`*CRC32`

Returns a 32-bit integer computed by applying a CRC (cyclic redundancy check) function to the selected text. This is the CRC function used by Ethernet, MPEG-2, PKZIP, GZIP, PNG, and many other applications. For example, the expression to compute the CRC value of the (first 1000 bytes of the) body of an HTTP request is: HTTP.REQ.BODY(1000).CRC32

`Returns:` num_at

`*DECODE_USING_TEXT_MODE`

Decodes the selected text using the currently configured text encoding methods like URLENCODED, BACKSLASH_ENCODED, PLUS_AS_SPACE, NOURLENCODED, NO_BACKSLASH_ENCODED and NO_PLUS_AS_SPACE. Text encoding methods are set using SET_TEXT_MODE method.

`Returns:` text_t

`*DECRYPT`

Decrypt the selected base64-encoded ciphertext using the configured encryptionParams.

`Returns:` text_t

`*DECRYPT` (binary_encoding_e in_encoding)

Decrypt the selected ciphertext using the configured encryptionParams.

`Parameters` (expressions not allowed) `:`

in_encoding- specifies how the input ciphertext is encoded. If the ciphertext is not encoded as specified, causes an Undef error.

`Returns:` text_t

`*DECRYPT` (text_t encryptionKey)

Decrypt the selected base64-encoded encrypted bytes using the configured encryption key.

`Parameters` (expressions not allowed) `:`

encryptionKey- identifies the encryptionKey object to provide the cipher method, mode, padding, key, encrypted format and optional initialization vector (IV).

`Returns:` text_t

`*DECRYPT` (text_t encryptionKey, binary_encoding_e in_encoding)

Decrypt the selected base64-encoded encrypted bytes using the configured encryption key.

`Parameters` (expressions not allowed) `:`

encryptionKey- identifies the encryptionKey object to provide the cipher method, mode, padding, key, encrypted format, and optional initialization vector (IV).

in_encoding- specifies how the input ciphertext is encoded. If the ciphertext is not encoded as specified, causes an Undef error.

`Returns:` text_t

`*DIGEST` (digest_method_e method)

Returns a byte sequence computed by applying the the specified message digest method to the selected text.

`Parameters` (expressions not allowed) `:`

method- digest method to apply to the input text

`Returns:` text_t

`*ENCRYPT`

Encrypt the selected plaintext bytes using the configured encryptionParams. The resulting ciphertext is base64-encoded.

`Returns:` text_t

`*ENCRYPT` (binary_encoding_e out_encoding)

Encrypt the selected plaintext bytes using the configured encryptionParams.

`Parameters` (expressions not allowed) `:`

out_encoding- specifies how the resulting ciphertext is encoded.

`Returns:` text_t

`*ENCRYPT` (text_t encryptionKey)

Encrypt the selected cleartext bytes using the configured encryption key.

`Parameters` (expressions not allowed) `:`

encryptionKey- identifies the encryptionKey object to provide the cipher method, mode, padding, key, encrypted format and optional initialization vector (IV).

`Returns:` text_t

`*ENCRYPT` (text_t encryptionKey, binary_encoding_e out_encoding)

Encrypt the selected cleartext bytes using the configured encryption key.

`Parameters` (expressions not allowed) `:`

encryptionKey- identifies the encryptionKey object to provide the cipher method, mode, padding, key, encrypted format and optional initialization vector (IV).

out_encoding- specifies how the resulting ciphertext is encoded.

`Returns:` text_t

`*ENDSWITH_ANY` (text_t patset_name)

Results in Boolean TRUE value if the Text ends with any of the strings that are bound to the patset or dataset named by the string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` bool_at

`*ENDSWITH_INDEX` (text_t patset_name)

Returns the numerical index of the matching string, if the Text ends with any of the strings that are bound to the patset or dataset named by the string argument. Returns 0 if there is no match. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` num_at

`*ENDSWITH` (text_t end)

Results in Boolean TRUE value if a suffix of the Text object matches the string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

end- String

`Returns:` bool_at

`*EQUALS_ANY` (text_t patset_name)

The EQUALS_ANY in this object overrides the Text EQUALS_ANY operator to operate on all the instances of the current header type. Returns Boolean TRUE if any of the patterns associated with input patset is equal to any instance of the header value. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Patset Name

`Returns:` bool_at

`*EQUALS_INDEX` (text_t patset_name)

The EQUALS_INDEX in this object overrides the Text EQUALS_INDEX operator to operate on all the instances of the current header type. Returns the index of the matching pattern associated with input patset is equal to any instance of the header value. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Patset Name

`Returns:` num_at

`*EQ` (text_t s)

Results in Boolean TRUE value if the Text object matches the input argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*EXISTS`

Returns TRUE if an instance of the current header type exists.

`Returns:` bool_at

`*GET_SIGNED16` (`uint` n, endian_e endianness)

Get the 16-bit signed binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

endianness- Select little or big endian

`Returns:` num_at

`*GET_SIGNED32` (`uint` n, endian_e endianness)

Get the 32-bit signed binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

endianness- Select little or big endian

`Returns:` num_at

`*GET_SIGNED8` (`uint` n)

Get the 8-bit signed binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

`Returns:` num_at

`*GET_UNSIGNED16` (`uint` n, endian_e endianness)

Get the 16-bit unsigned binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

endianness- Select little or big endian

`Returns:` num_at

`*GET_UNSIGNED32` (`uint` n, endian_e endianness)

Get the 32-bit unsigned binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

endianness- Select little or big endian

`Returns:` unsigned_long_at

`*GET_UNSIGNED64` (`uint` n, endian_e endianness)

Get the 64-bit unsigned binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

endianness- Select little or big endian

`Returns:` unsigned_long_at

`*GET_UNSIGNED8` (`uint` n)

Get the 8-bit unsigned binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

`Returns:` num_at

`*GET_URLSET_METADATA` (text_t urlset_name)

Returns metadata value corresponding to pattern in the urlset. The matching is case-insensitive for domains, but case-sensitive for paths. If no pattern is matched within the urlset, the return value is a NULL string. For example:

- HTTP.REQ.HOST.APPEND(HTTP.REQ.URL).GET_URLSET_METADATA("urlset_forbidden") returns value when the combined domain and URL is looked up in the urlset whose name is "urlset_forbidden".

`Parameters` (expressions not allowed) `:`

urlset_name- urlset name

`Returns:` text_t

`*GE` (text_t s)

Results in Boolean TRUE value if the Text object is greater than or equal to the input argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*GRPC`

Interprets a text_t string as a Protocol Buffer (protocol_buffer_t type). Example: HTTP.REQ.BODY(1000).GRPC.STRING(1).EQ("bookname")

`Returns:` protocol_buffer_t

`*GT` (text_t s)

Results in Boolean TRUE value if the Text object is greater than the input argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*HASH`

Returns a positive 31 bit integer value computed by applying a proprietary NetScaler hash function to the selected text. This function is not case- sensitive and ignores whitespaces. For example, applying the HASH function to two strings "Ab c" and "abc" would produce the same value. This function should not be used for security purposes; use instead the DIGEST function with one of the standard digest methods.

`Returns:` num_at

`*HMAC` (text_t hmacKey)

Returns a byte sequence computed by applying the HMAC (Hash Message Authenticastion Code) function to the selected text using the configured HMAC key.

`Parameters` (expressions not allowed) `:`

hmacKey- indentifies the hmacKey object to provide the digest (hash) method and the key.

`Returns:` text_t

`*HMAC` (text_t hmacKey, binary_encoding_e out_encoding)

Returns a byte sequence computed by applying the HMAC (Hash Message Authenticastion Code) function to the selected text using the configured HMAC key .

`Parameters` (expressions not allowed) `:`

hmacKey- indentifies the hmacKey object to provide the digest (hash) method and the key.

out_encoding- specifies how the resulting HMAC is encoded.

`Returns:` text_t

`*HTML_XML_SAFE`

Apply XML safe transform and select text.

Converts '<', '>' and '&' in the input text to '<', '>' and '&' respectively; other characters in the input are not modified. This transform safeguards against XSS based attacks. This is a read only operation.

`Returns:` text_t

`*HTTP_HEADER_SAFE`

Apply Header safe transform and select text. Converts all new line ('\\n') characters present in the input text to '%0A' so that they can safely be used in HTTP headers. This transform safeguards against response-splitting attacks. This is a read only operation.

`Returns:` text_t

`*HTTP_URL_SAFE`

Apply URL safe transform and select text. Converts URL unsafe characters to corresponding '%xx' values and retains the rest. This is a read only operation.

```
Based on RFC2396, following are considered URL safe characters:

    Alpha-numeric characters: a-z, A-Z, 0-9

    Hyphen and underscore: "-", "_"

    Dot: "."

    Exclamation mark: "!"

    Tilde: "~"

    Asterix: "&ast;"

    Single quote: "'"

    Open and close parentheses: "(", ")"

    Semi-colon: ";"

    Colon: ":"

    At symbol: "@"

    Question mark: "?"

    Equals: "="

    Dollar: "$"

    Percent: "%"
```

```
    Ampersand: "&"

    Plus: "+"

    Comma: ","

    Forward slash: ".html"
```

The rest are converted to %XX encoding, 'XX' is the hex-based representation of the input character. If the requirement is to encode all but URL unreserved characters, please consider using URL_RESERVED_CHARS_SAFE method.

`Returns:` text_t

`*INSTANCE` (`uint` lineno)

An HTTP header can have multiple occurrences. INSTANCE(0) will select the last header line of the current type, INSTANCE(1) will select the last but one header line and so on. The counting goes backward. Only the last 15 instances of a header are accessible. Therefore Instance Number cannot be greater than 14.

HTTP/1.1 200 OK\\r\\n MyHdr: abc\\r\\n Content-Length: 200\\r\\n MyHdr: def\\r\\n \\r\\n

For example: HTTP.RES.HEADER("MyHdr").INSTANCE(1) will return a Text object referring to "MyHdr: abc\\r\\n". It can not be used in HTTP response processing contexts.

`Parameters` (expressions not allowed) `:`

lineno- Instance Number

`Returns:` text_t

`*IS_BOOL_AT`

Results in Boolean TRUE value if the Text is of boolean type.

`Returns:` bool_at

`*IS_DOUBLE_AT`

Results in Boolean TRUE value if the Text is of double data type.

`Returns:` bool_at

`*IS_IPV6_AT`

Results in Boolean TRUE value if the Text is of IPv6 data type.

`Returns:` bool_at

`*IS_IPV6_SUBNET_AT`

Results in Boolean TRUE value if the Text is of IPv6 subnet data type.

`Returns:` bool_at

`*IS_IP_AT`

Results in Boolean TRUE value if the Text is of IPv4 data type.

`Returns:` bool_at

`*IS_MAC_ADDRESS_AT`

Results in Boolean TRUE value if the Text is of mac address data type.

`Returns:` bool_at

`*IS_NUM_AT`

Results in Boolean TRUE value if the Text is of number type.

`Returns:` bool_at

`*IS_NUM_AT` (num_format_e format)

Results in Boolean TRUE value if the Text is of number type with given input base.

`Parameters` (expressions not allowed) `:`

format- number format

`Returns:` bool_at

`*IS_STRINGMAP_KEY` (text_t string_map_name)

Returns true if the string that it operates on is present in the string map. Text mode IGNORECASE, NOIGNORECASE - controls whether key lookup in string map is case sensitive or not. For example:

- HTTP.REQ.URL.IS_STRINGMAP_KEY("url_stringmap") returns true if value of HTTP.REQ.URL is present as key in the string map whose name is "url_stringmap".
- HTTP.REQ.URL.SET_TEXT_MODE(IGNORECASE). IS_STRINGMAP_KEY("url_stringmap") returns true if value of HTTP.REQ.URL is present as key in the string map whose name is "url_stringmap". Key lookup in this case is done case-insensitively.

`Parameters` (expressions not allowed) `:`

string_map_name- identifies the string map.

`Returns:` bool_at

`*IS_TIME_AT`

Results in Boolean TRUE if the Text follows any of the standard time formats given below, otherwise false. Tue, 05 Nov 1994 08:12:31 GMT RFC822 Tuesday, 05-Nov-94 08:12:31 GMT RFC850 Tue Nov 4 08:12:31 1994 asctime

`Returns:` bool_at

`*IS_UNSIGNED_LONG_AT`

Results in Boolean TRUE value if the Text is of unsigned long data type.

`Returns:` bool_at

`*IS_UNSIGNED_LONG_AT` (num_format_e format)

Results in Boolean TRUE value if the Text is of unsigned long data type with given input base.

`Parameters` (expressions not allowed) `:`

format- number format

`Returns:` bool_at

`*JWT_VERIFY_CERTKEY` (text_t certkey_name)

Verifies the signature on the input JSON Web Token (JWT), using the RSA public key in the X.509 certificate in the specified certkey object. The token has the format HEADER.PAYLOAD.SIGNATURE where

- HEADER is a base64-encoded JSON structure indicating a signature algorithm and token type, e.g.'{"alg":"RS256","typ":"JWT"}'

- PAYLOAD is a base64-encoded JSON structure with asserted claims, e.g. '{"loggedInAs":"admin","iat":1422779638}'
- SIGNATURE is the base64-encoded bytes for the signature on HEADER.PAYLOAD.

Returns true if the signature is verified for the header and payload using the specified public key; false if the signature is not verified

`Parameters``:`

certkey_name- identifies the certkey object containing an X.509 certificate holding the RSA public key. Results in an Undef error if the certkey object does not exist or does not contain an X.509 certificate with an RSA public key, if the token is not correctly formatted, or if the verification operation cannot complete.

`Returns:` bool_at

`*JWT_VERIFY_XML` (text_t xml_pkey)

Verifies the signature on the input JSON Web Token (JWT), using the RSA public key supplied by the specified XML element. The token has the format HEADER.PAYLOAD.SIGNATURE where

- HEADER is a base64-encoded JSON structure indicating a signature algorithm and token type, e.g.'{"alg":"RS256","typ":"JWT"}'
- PAYLOAD is a base64-encoded JSON structure with asserted claims, e.g. '{"loggedInAs":"admin","iat":1422779638}'
- SIGNATURE is the base64-encoded bytes for the signature on HEADER.PAYLOAD.

Returns true if the signature is verified for the header and payload using the specified public key; false if the signature is not verified

`Parameters``:`

xml_pkey- an expression that supplies an <RSAKeyValue> element with the public key. Results in an Undef error if the XML element is invalid or does not correctly specify an RSA public key, if the token is not correctly formatted, or if the verification operation cannot complete.

`Returns:` bool_at

`*LENGTH`

Results in a Number Value that is the number of characters (not bytes) in the Text object.

`Returns:` num_at

`*LE` (text_t s)

Results in Boolean TRUE value if the Text object is less than or equal to the input argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*LOCATION_LONG`

Get the location qualifier from CLIENT.IP.SRC.LOCATION.GET(n) (ISO short name) and then convert it to human readable long name. This conversion is valid only for country names. Correct Country qualifier value (number) in GET(n) is left up to the user as qualifiers are user configurable. Expression example: CLIENT.IP.SRC.LOCATION.GET(1).LOCATION_LONG For example: Data from each expression CLIENT.IP.SRC.LOCATION: NA.US.California.SantaClara.*.* CLIENT.IP.SRC.LOCATION.GET(1): US CLIENT.IP.SRC.LOCATION.GET(1).LOCATION_LONG: United States

`Returns:` text_t

`*LT` (text_t s)

Results in Boolean TRUE value if the Text object is less than the input argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*MAP_STRING_DEFAULT_TO_KEY` (text_t string_map_name)

Returns the value corresponding to the key in the string map. This is similar to the MAP_STRING method, but if the key is not present then instead of returning a null string, it returns the key itself. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed)`:`

string_map_name- identifies the string map.

`Returns:` text_t

`*MAP_STRING` (text_t string_map_name)

Returns value corresponding to key in the string map. Key is the string that it is given as input. Text mode IGNORECASE, NOIGNORECASE - controls whether key lookup in string map is case sensitive or not. For example:

- HTTP.REQ.URL.MAP_STRING("url_stringmap") returns value when the value of HTTP.REQ.URL is used as key in the string map whose name is "url_stringmap".
- HTTP.REQ.URL.SET_TEXT_MODE(IGNORECASE). MAP_STRING("url_stringmap") returns value when the value of HTTP.REQ.URL is used as key in the string map whose name is "url_stringmap". Key lookup in this case is done case-insensitively.

`Parameters` (expressions not allowed) `:`

string_map_name- identifies the string map.

`Returns:` text_t

`*MARK_SAFE`

Mark the PIXL expression safe without applying any safe transform.

`Returns:` text_t

`*MAX` (text_t s)

Compares the string argument with the current string and returns the max string. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*MIN` (text_t s)

Compares the string argument with the current string and returns the min string. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*NE` (text_t s)

Results in Boolean TRUE value if the Text object is not equal to the input argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*NORMALIZE_URL`

Normalize URL. Normalizes a URL by doing "percent" decoding. See the description for URLENCODED in the SET_TEXT_MODE function. This performs the equivalent of SET_TEXT_MODE(URLENCODED).DECODE_USING_TEXT_MODE, except that it does not change the value of the current text mode.

`Returns:` text_t

`*PKEY_ENCRYPT_PEM_NO_PADDING` (text_t pem_pkey)

Encrypts the input text using the RSA public key provided by the PEM string and RSA_NO_PADDING padding method. The input text to be encrypted cannot be longer than the public key length minus 11 bytes for padding. For example, for a 1024-bit (128 byte) key, the input text cannot be longer than 128 - 11 = 117 bytes. An Undef error will occur if the input text is too long. A null input will also cause an Undef error. Returns the (unencoded binary) encrypted text, which is typically base-64 encoded for use in a message.

`Parameters``:`

pem_pkey- a text expression that supplies a RSA public key in the PEM format. If the text value is not a valid PEM RSA PUBLIC KEY encoding, an Undef error will occur. Example (a 1024-bit public key):

```
"-----BEGIN RSA PUBLIC KEY-----" +

"MIGJAoGBAKl5vgQEj73Kxp+9yn1v5gPR1pnc4oLM2a0kaWwBOsB6rzCIy6znwnvw" +

"CY1xRvQhRlJSAyJbloL7wZFIJ2FOR8Cz+8ZQWXU2syG+udi4EnWqLgFYowF9zK+o" +
```

```
"79az597eNPAjsHZ/C2oL/+6qY5a/f1z8bQPrHC4GpFfAEJhh/+NnAgMBAAE=" +

"-----END RSA PUBLIC KEY-----"
```

`Returns:` text_t

`*PKEY_ENCRYPT_PEM` (text_t pem_pkey)

Encrypts the input text using the RSA public key provided by the PEM string and the RSA_PKCS1_PADDING padding method. The input text to be encrypted cannot be longer than the public key length minus 11 bytes for padding. For example, for a 1024-bit (128 byte) key, the input text cannot be longer than 128 - 11 = 117 bytes. An Undef error will occur if the input text is too long. A null input will also cause an Undef error. Returns the (unencoded binary) encrypted text, which is typically base-64 encoded for use in a message.

`Parameters``:`

pem_pkey- a text expression that supplies a RSA public key in the PEM format. If the text value is not a valid PEM RSA PUBLIC KEY encoding, an Undef error will occur. Example (a 1024-bit public key):

```
"-----BEGIN RSA PUBLIC KEY-----" +

"MIGJAoGBAKl5vgQEj73Kxp+9yn1v5gPR1pnc4oLM2a0kaWwBOsB6rzCIy6znwnvw" +

"CY1xRvQhRlJSAyJbloL7wZFIJ2FOR8Cz+8ZQWXU2syG+udi4EnWqLgFYowF9zK+o" +

"79az597eNPAjsHZ/C2oL/+6qY5a/f1z8bQPrHC4GpFfAEJhh/+NnAgMBAAE=" +

"-----END RSA PUBLIC KEY-----"
```

`Returns:` text_t

`*PKEY_SIGN_CERTKEY` (text_t certkey_name)

Generates a binary digital signature using the SHA-256 message digest function and an RSA private key from the specified SSL certKey object.

`Parameters``:`

certkey_name- identifies the configured certKey object. Results in an Undef error if the certkey object does not exist or does not contain an RSA private key, or if the signing operation cannot complete.

`Returns:` text_t

`*PKEY_SIGN_XML` (text_t xml_pkey)

Generates a binary digital signature using the SHA-256 message digest function and an RSA private key from the specified XML element.

`Parameters``:`

xml_pkey- an expression that supplies an <RSAKeyValue> element with the private key. Example: <RSAKeyValue> <Modulus>qXm+BASPvcrGn73KfW/
mA9HWmdzigszZrSRpbAE6wHqvMIjLrOfCe/
AJjXFG9CFGUlIDIluWgvvBkUgnYU5HwLP7xlBZdTazIb652LgSdaouAVijAX3Mr6jv1rPn3t408COwdn8Lagv/
7qpjlr9/XPxtA+scLgakV8AQmGH/42c=</Modulus> <Exponent>AQAB</Exponent>"zNjysxcIJV/
J9cTpIgPp2/x1IXHT5GTH8OMuNad0qtRSLjU1QYUmmkm9QcJJAN+7h8FEXWGabySUzBrHj/
IEbw=="
<DP>QavUDQLLQpnPJXtVAo6CYhxOMCd68mwTxYKKNLjmC0pd54SFHllTLPE1FZU5EjK6q3nCeijonpfH+XX
DP> <DQ>EiXOKouJzzXTQJC3TqomF7Uf81yQNxWumOqnd11kepXgyfMwyqMvLlAGEkNSEF/
Bz18R3Wv+MIZ/IC3nLBt2xQ==</DQ>
<InverseQ>ocuCmz36CP+N2aGqxaU+BKD5+3RLgRq9LFhULEz2jKx0iV9r76jsAxn3sLcTYYO9eqRPy2cz74AU
nw==</InverseQ> <D>fTBD773a3GzcmgVdfZlaBLpN1ux2mf5uUVrTUQf7eVFm9egm4/
tzC5A9zjC+I/oscwTH8epL3UfRLdtp05Q6pWfJBXEnGo0QmOFFBK4pLx/
5JJpPGZ69ovDFEVOUHyiCfKE/g97T4WX3us0nFe1272zwGlHarM1YYwvfeE08UdE=</D> </
RSAKeyValue> Results in an Undef error if the XML element is invalid or does not correctly specify an RSA private key, or if the signing operation cannot complete.

`Returns:` text_t

`*PKEY_VERIFY_CERTKEY` (text_t certkey_name, text_t signature)

Verifies if the input text matches the specified signature generated using the SHA-256 messge digest function and the RSA private key associated with the specified RSA public key in the X.509 certificate in the specified certKey object. Returns true if the signature is verified, false otherwise.

`Parameters``:`

certkey_name- identifies the certkey object containing an X.509 certificate holding the RSA public key.

signature- the binary signature. Results in an Undef error if the certkey object does not exist or does not contain an X.509 certificate with an RSA public key, or if the verification operation cannot complete.

`Returns:` bool_at

`*PKEY_VERIFY_XML` (text_t xml_pkey, text_t signature)

Verifies if the input text matches the specified signature generated using the SHA-256 messge digest function and the RSA private key associated with the RSA public key supplied by the specified XML element. Returns true if the signature is verified, false otherwise.

`Parameters``:`

xml_pkey- an expression that supplies an <RSAKeyVAlue> element with the public key. Example: <RSAKeyValue> <Modulus>qXm+BASPvcrGn73KfW/mA9HWmdzigszZrSRpbAE6wHqvMIjLrOfCe/AJjXFG9CFGUlIDIluWgvvBkUgnYU5HwLP7xlBZdTazIb652LgSdaouAVijAX3Mr6jv1rPn3t408COwdn8Lagv/7qpjlr9/XPxtA+scLgakV8AQmGH/42c=</Modulus> <Exponent>AQAB</Exponent> </RSAKeyValue>

signature- the binary signature. Results in an Undef error if the XML element is invalid or does not correctly specify an RSA public key, or if the verification operation cannot complete.

`Returns:` bool_at

`*PREFIX` (`char` c, `uint` i)

Select a prefix of the Text. The selected prefix is the longest prefix that has at most Count (2nd argument) occurrences of character in the 1st argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

c- Character

i- Count

`Returns:` text_t

`*PREFIX` (`uint` i)

Select a prefix of the Text. The length of the prefix is equal to the number in the argument. If there aren't enough characters in the Text object then the entire Text is selected.

`Parameters``:`

i- Prefix Length

`Returns:` text_t

`*REGEX_MATCH` (`re` regex)

The REGEX_MATCH operator in this object overrides the Text REGEX_MATCH operator to operate on all the instances of the current header type. Returns Boolean TRUE if the input regular expression matches any instance of the header value. The order in which the header instances will be matched is from the last to the first.

The regular expression has to be of the format: `re<delimiter>regular expression<same delimiter>`

The regular expression cannot be bigger than 1499 characters.

The regular expression should be acceptable by the PCRE regular expression library. Look at http://www.pcre.org/pcre.txt for documentation on the regular expression syntax. In particular, look at the pcrepattern man page.

There are some differences in the allowed syntax w.r.t PCRE syntax. Backreferences are not allowed. It is recommended to not use recursive regular expressions. The dot metacharacter matches newlines also. Unicode is not supported. SET_TEXT_MODE(IGNORECASE) overrides the (?i) internal option specified in the regular expression.

The PCRE library configuration can be seen in the system log, after executing 'nsapimgr -B" call ns_pixl_regex_show_config()"' at the shell prompt.

Some examples:

- HTTP.REQ.HOSTNAME.REGEX_MATCH(re/\[\[:alpha:\]\]+(abc){2,3}/)
- HTTP.REQ.URL.SET_TEXT_MODE(URLENCODED).REGEX_MATCH(re#(a*b+c*)#)
- HTTP.REQ.URL.REGEX_MATCH(re/a(?i)b/) matches ab and aB
- HTTP.REQ.URL.SET_TEXT_MODE(IGNORECASE).REGEX_MATCH(re/ab/) matches ab, aB, Ab and AB

- HTTP.REQ.BODY.REGEX_MATCH(re/(?ixm) (\^ab (.*) cd$) /) does a case-insensitive, multiline match where the dot metacharacter matches newline also. The regex itself can contain whitespace which will be ignored during the matching (x - extended regex).

This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

regex- Regular Expression

`Returns:` bool_at

`*REGEX_REPLACE` (`re` regex, text_t replacement, replacemode_e mode)

Selects the text that matches the given regular expression argument and replaces it with the the text given in the second argument. The third argument specifies whether the first match is only replaced when multiple matches occur in the text or all matches are replaced. The match may occur anywhere within the text - if you wish to "anchor" this, use "\^" at the start of the regex and/or "$" at the end of the regex. When the regular expression does not match the given string then the same string is returned.

For example: HTTP.RES.BODY(999).REGEX_REPLACE(re!\\bpassword:\\s*\\b!, "password: ***", ALL) will replace all occurrences of "password:" with "password: ***" This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

regex- Regular Expression

replacement- String to replace the match

mode- Mode of replacement

`Returns:` text_t

`*REGEX_SELECT` (`re` regex)

The REGEX_SELECT operator in this object overrides the Text REGEX_SELECT operator to operate on all the instances of the current header type. Selects the Text that matches the input regular expression in any instance of the header value. The order in which the header instances will be matched is from the last to the first.

For example: HTTP.REQ.HEADER("via").REGEX_SELECT(re!NS-CACHE-\\d\\.\\d:\\s*\\d{1,3}!) will select "NS-CACHE-7.0: 70" This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

regex- Regular Expression

`Returns:` text_t

`*REPEAT` (`uint` i)

Produces a string which contains 'i' sequential copies of the input string.

`Parameters``:`

i- the number of times to repeat the string (0 or more)

`Returns:` text_t

`*SET_CHAR_SET` (charset_e charset)

Set the character set to use for subsequent functions that use text.

`Parameters` (expressions not allowed) `:`

charset- Character Set

`Returns:` http_set_cookie_t

`*SET_TEXT_MODE` (textmode_e mode)

The mode setting of a Text object controls the behavior of many Text operations. The Text mode settings may also control the behavior of some operations in objects (like List) that build upon the Text object. IGNORECASE, NOIGNORECASE - controls whether string comparison is case sensitive or not. URLENCODED - If set then all Text operations are carried out after translating all %HH or %uHHHH encodings in the underlying byte stream. 1. %HH will be translated to the character Y where HH denotes the ascii value of character Y in hexadecimal. For example, the encoded text "http%3a/.html" will be decoded to "http:/.html" 2. %uWWHH will be translated to the character sequence YZ where WW denotes the ascii value of character Y in hexadecimal and HH denotes the ascii value of character Z in hexadecimal. For example, the encoded text "http%u3a2f.html" and "http%u003a/.html" will both be decoded to"http:/.html" NOURLENCODED - Indicates that no percent encodings are present in the Text object. No percent decoding will be performed on the Text object. PLUS_AS_SPACE - If set then all Text operations are carried out

after converting occurrences of the plus character to whitespace. For example, the text "hello+world" will be decoded to "hello world" NO_PLUS_AS_SPACE - If set, then the plus character will not be converted to whitespace in the Text object. BACKSLASH_ENCODED - If set, then all Text operations are carried out after performing the following operations: 1. \\XXX will be translated to the character Y where XXX denotes the ascii value of character Y in octal. The valid range of octal values for this type of encoding is \\0 to \\377. For example, the encoded text "http\\72/.html" and "http\\072/.html" will both be decoded to "http:/.html" 2. \\xHH will be translated to the character Y where HH denotes the ascii value of character Y in hexadecimal. For example, the encoded text "http\\x3a/.html" will be decoded to "http:/.html" 3. \\\\uWWXX will be translated to the character sequence YZ where WW denotes the ascii value of character Y in hexadecimal and XX denotes the ascii value of character Z in hexadecimal. For example, the encoded text "http%u3a2f.html" and "http%u003a/.html" will both be decoded to"http:/.html" 4. Occurences of "\\b", "\\n", "\\t", "\\f" and "\\r" are translated to the corresponding ascii characters. NO_BACKSLASH_ENCODED - If set, then backslash decoding will not be performed on the Text object. BAD_ENCODE_RAISE_UNDEF - If set, then UNDEF is raised if either the URLENCODED or BACKSLASH_ENCODED mode is set and a bad encoding corresponding to the specified encoding mode is encountered. NO_BAD_ENCODE_RAISE_UNDEF - If set, then UNDEF will not be raised when a bad encoding is encountered in the Text object. The Text operations operate on characters (as opposed to operating on bytes). By default a single byte represents a character using the ASCII encoding. But if URLENCODED mode is set then 3 bytes may represent a character. A PREFIX(3) operation will select the first 3 characters in the Text object. That means it may select up to 9 bytes for URLENCODED Text object. In the case of multibyte decodings as a result of %uXXXX or \\\\uXXXX, Text operations which attempt to treat the multiple decoded bytes as distinct characters are not allowed.

`Parameters` (expressions not allowed) `:`

mode- Text Mode

`Returns:` http_set_cookie_t

`*SKIP` (`char` c, `uint` i)

Select the Text after skipping over a prefix of the current Text. The skipped over prefix is the longest prefix that has at most Count (2nd argument) occurrences of character in the 1st argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

c- Character

i- Count

`Returns:` text_t

`*SKIP` (`uint` i)

Select the Text after skipping over a prefix in the current Text. The length of the prefix is equal to the number in the argument. If there aren't enough characters in the Text object then the entire Text is skipped over.

`Parameters` (expressions not allowed) `:`

i- Prefix Length

`Returns:` text_t

`*STARTSWITH_ANY` (text_t patset_name)

Results in Boolean TRUE value if the Text starts with any of the strings that are bound to the patset or dataset named by the string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` bool_at

`*STARTSWITH_INDEX` (text_t patset_name)

Returns the numerical index of the matching string, if the Text starts with any of the strings that are bound to the patset or dataset named by the string argument. Returns 0 if there is no match. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` num_at

`*STARTSWITH` (text_t start)

Results in Boolean TRUE value if a prefix of the Text object matches the string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

start- String

`Returns:` bool_at

`*STRIP_CHARS` (text_t s)

From the selected text remove the characters specified in the string.

For example: Say the selected text is / "foo.xyz=bar" /. Then on executing STRIP_CHARS('.=') or STRIP_CHARS('..=') the selected text will become /fooxyzbar /. Note that repeating character has same effect as it would be if it present only once. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*STRIP_END_CHARS` (text_t s)

Selects the Text after stripping off characters in the end of the current Text object.

For example: Say the selected text is / "foo.xyz=bar" /. Then on executing STRIP_END_CHARS('ar') the selected text will become /foo.xyz=b /. Note that repeating character has same effect as it would be if it present only once. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*STRIP_END_WS`

Selects the Text after stripping off white space in the end of the current Text object.

`Returns:` text_t

`*STRIP_START_CHARS` (text_t s)

Selects the Text after stripping off characters in the beginning of the current Text object.

For example: Say the selected text is / "foo.xyz=bar" /. Then on executing STRIP_START_CHARS('of') the selected text will become /.xyz=bar /. Note that repeating character has same effect as it would be if it present only once. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*STRIP_START_WS`

Selects the Text after stripping off white space in the beginning of the current Text object.

`Returns:` text_t

`*SUBSTR_ANY` (text_t patset_name)

Select any one sub-string that matches any string in the given patset or dataset. The patset cannot have strings longer than 255 characters. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` text_t

`*SUBSTR` (`uint` start, `uint` len)

Select the Text object of the given length at the given offset. Offset it 0 based. If there aren't enough characters after the offset then all the remaining characters are selected.

`Parameters``:`

start- Offset

len- Length

`Returns:` text_t

`*SUBSTR` (text_t s)

The SUBSTR operator in this object overrides the Text SUBSTR operator to operate on all the instances of the current header type. Selects Text that matches the input string argument. The order in which the instances of the header are matched is from the last instance to the first.

HTTP/1.1 200 OK\\r\\n MyHdr: 111abc\\r\\n Content-Length: 200\\r\\n MyHdr: 111def\\r\\n \\r\\n

For example: HTTP.RES.HEADER("MyHdr").SUBSTR("111") selects "111" in the last instance of MyHdr, the one with value "111def". This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*SUFFIX` (`char` c, `uint` i)

Select a suffix of the Text. The selected suffix is the longest possible suffix containing at most Count (2nd arg) occurrences of the character in the 1st argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

c- Character

i- Count

`Returns:` text_t

`*SUFFIX` (`uint` i)

Select a suffix of the Text. The length of the suffix is equal to the number in the argument. If there aren't enough characters in the Text object then the entire Text is selected.

`Parameters``:`

i- Suffix Length

`Returns:` text_t

`*TO_LOWER`

Converts the selected text to lower case.

For example, the string "ABCd" is converted to "abcd"

`Returns:` text_t

`*TO_UPPER`

Converts the selected text to upper case.

For example, the string "abcD" is converted to "ABCD"

`Returns:` text_t

`*TRUNCATE` (`char` c, `uint` i)

Select the Text after truncating a suffix from the current Text object. The truncated suffix is the longest possible suffix containing at most Count (2nd arg) occurrences of the character in the 1st argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

c- Character

i- Count

`Returns:` text_t

`*TRUNCATE` (`uint` i)

Select the Text after truncating a suffix of the Text. The length of the suffix truncated is equal to the number in the argument. If there aren't enough characters in the Text then then all the characters are truncated.

`Parameters``:`

i- Suffix Length

`Returns:` text_t

`*TYPECAST_AVP_T`

Convert text_t to avp_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (avp_t : Operations that can be performed on the returned AVPs.

`Note:` An AVP can have multiple instances in a Diameter message. However, the system can access only the first 16 instances.

`Example:`

- To get the first value of AVP code 266 from a request, use: DIAMETER.REQ.AVP(266).VALUE(0).
- To get the fourth value of AVP code 266 from a request, use: DIAMETER.REQ.AVP(266).VALUE(3).
- To check if AVP code 1000 in the response has the vendor-specific bit set, use: DIAMETER.RES.AVP(1000).IS_VENDOR_SPECIFIC.

)

`Returns:` avp_t

`*TYPECAST_AVP_UNUM_T`

Convert text_t to avp_unum_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (avp_unum_t : In Diameter AVP based expressions can be written as DIAMETER.REQ.AVP(<avpcode>). For example Auth-Application-Id AVP (AVP code 258) can be extracted as DIAMETER.REQ.AVP(258) For few of the important AVPs we provide aliases. For example this AVP based expression can also be written as DIAMETER.REQ.AUTH_APPLICATION_ID. This expression returns either a object of class avp_t or returns a numerical value (object of class unsigned_long_at). The numerical value for this object is derived from the value in first instance of the AVP.)

`Returns:` avp_unum_t

`*TYPECAST_BOOL_AT`

Convert text_t to bool_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (bool_at : Boolean Operations)

`Returns:` bool_at

`*TYPECAST_COOKIE_T`

Convert text_t to cookie_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (cookie_t : The HTTP Cookie type provides operations for a cookie as it appears in the Set-Cookie and Set-Cookie2 header. In this type the Name-Value List operations are also available. The first delimiter is = and the element delimiter is ;. Multiple consecutive ; are treated as one. (Same as applying the method IGNORE_EMPTY_ELEMENTS on a Name-Value List.) You can use the Name-value List operations to access cookie attributes.

The name comparison for all list operations is case insensitive. In this type Text operations are also available. Each cookie begins with a COOKIE_NAME=COOKIE_VALUE pair followed by zero or more semi-colon separated attribute-value pairs. If an attribute appears more than once in a cookie, the value associated with the first appearance of the attribute is returned.

Format Cookie: Cookie1=Value;Version=decimal;Value;Domain=Value;Path=Value)

`Returns:` cookie_t

`*TYPECAST_DIAMETER_FLAG_T`

Convert text_t to diameter_flag_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (diameter_flag_t : Provides operation to treat the underlying 1 byte as set of bit flags. then set/unset/test/reset_all operations can be done on flag)

`Returns:` diameter_flag_t

`*TYPECAST_DNS_DOMAINNAME_T`

Convert text_t to dns_domainname_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (dns_domainname_t : This object provides operations for parsing the DNS domain name as it appears at various places in the DNS data. The format is abc.foo.com.)

`Returns:` dns_domainname_t

`*TYPECAST_DNS_FLAG_T`

Convert text_t to dns_flag_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (dns_flag_t : Provides operations to test/set/unset a flag in dns header.)

`Returns:` dns_flag_t

`*TYPECAST_DOUBLE_AT`

Convert text_t to double_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_at : Double Value)

`Returns:` double_at

`*TYPECAST_DOUBLE_T` (double_format_e format)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error.)

`Parameters` (expressions not allowed) `:`

format- Format

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, double_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, ip_address_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, num_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, time_local_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, time_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, unsigned_long_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_HTTP_CACHE_CONTROL_T`

Convert text_t to http_cache_control_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_cache_control_t : This object provides for the ability to work on HTTP Cache-Control headers. The name comparison for all list operations is case insensitive.)

`Returns:` http_cache_control_t

`*TYPECAST_HTTP_CONTENT_LENGTH_T`

Convert text_t to http_content_length_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_content_length_t : The HTTP.REQ.CONTENT_LENGTH or HTTP.RES.CONTENT_LENGTH object can be treated as a HTTP Header or as a Number. The numerical value for this object is derived from the value in the last instance of the Content-Length header.)

`Returns:` http_content_length_t

`*TYPECAST_HTTP_COOKIE_T`

Convert text_t to http_cookie_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_cookie_t : This object provides operations for parsing the HTTP cookie header. The name-value pair is derived from the value in the last instance of Cookie header. The format is Cookie : name0=value0; name1=value1; An HTTP Cookie header can have multiple occurrences. COUNT will return a Number containing how many headers of the current type exist. The name comparison for all list operations is case insensitive. The system does not keep track of more than 15 HTTP headers. The result will be undefined if there are more than 15 instances of the header.)

`Returns:` http_cookie_t

`*TYPECAST_HTTP_DATE_T`

Convert text_t to http_date_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_date_t : The HTTP.REQ.DATE or HTTP.RES.DATE object can be treated as a HTTP header or a Time object. The Time value is derived from the value in the last instance of the Date header. The date formats supported are RFC 822 (updated by RFC 1123), RFC 1036 (obsoletes RFC850) and ANSI C asctime() formats.)

`Returns:` http_date_t

`*TYPECAST_HTTP_HEADER_T` (text_t name)

Convert text_t to http_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_header_t : When typecasting a Text object to HTTP Header a header name must be provided.For example: HTTP.REQ.HEADER("MyHdr").TYPECAST_HTTP_HEADER_T("InHdr"))

`Parameters` (expressions not allowed) `:`

name- Header Name

`Returns:` http_header_t

`*TYPECAST_HTTP_HOSTNAME_T`

Convert text_t to http_hostname_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_hostname_t : This object provides operations for parsing the HTTP hostname as it appears at various places in the HTTP protocol data. The format is abc.foo.com:8080.)

`Returns:` http_hostname_t

`*TYPECAST_HTTP_METHOD_T`

Convert text_t to http_method_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_method_t : This object provides Text operations and HTTP Request Method Enum operations on the HTTP request method.)

`Returns:` http_method_t

`*TYPECAST_HTTP_SET_COOKIE_T`

Convert text_t to http_set_cookie_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_set_cookie_t : HTTP.RES.SET_COOKIE provides operations for parsing and operating on the SET-COOKIE header that is present in the HTTP response. HTTP Set-Cookie header supports Text and HTTP Header operations. For most Text operations the value in the last Set-Cookie header is selected. HTTP Set-Cookie header also supports special operations to extract cookies from the response. It is assumed that there will be only one cookie in a Set-Cookie header.)

`Returns:` http_set_cookie_t

`*TYPECAST_HTTP_URL_T`

Convert text_t to http_url_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_url_t : HTTP.REQ.URL provides operations for parsing and operating on the URL that is present in the first line of the HTTP request header. The supported format is \[<protocol>://<hostname>\]<path>?<query>. The Text object backing a HTTP URL object has the Text Mode set to URLENCODED by default.)

`Returns:` http_url_t

`*TYPECAST_HTTP_VERSION_T`

Convert text_t to http_version_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_version_t : HTTP.REQ.VERSION or HTTP.RES.VERSION provide operations to extract HTTP version information.)

`Returns:` http_version_t

`*TYPECAST_IPV6_ADDRESS_AT`

Convert text_t to ipv6_address_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ipv6_address_at : Provides operations for the 128-bit IPv6 address value. Some general information regarding IPv6 expressions: IPv6 PIXL expressions can be combined with other PIXL expressions using the '+' operator. The output is expected to be the concatenation of the string representations of the individual PIXL expressions. No other operator other than '+' is expected to work when any of the operands is an IPv6 PIXL expression. Also, IPv6 PIXL expressions can be combined with any other type of PIXL expression except a PIXL expression that produces a bool result. In other words, if A and/or B are two IPv6 addresses, A+B should result in the string AB. When one of A or B is an IPv6 address, the other can only be a number or a string and not a boolean. Further, when A and/or B is an IPv6 address, the only operator allowed between them is '+'.

Example: Let the client source IPv6 address be ABCD:1234::ABCD. Let the server destination IPv4 address be 10.100.10.100. Then the expression CLIENT.IPV6.SRC + SERVER.IP.DST should produce the output "ABCD:1234::ABCD10.100.10.100". Similarly, CLIENT.IPV6.SRC + 5 should produce the result ABCD:1234::ABCD5)

`Returns:` ipv6_address_at

`*TYPECAST_IPV6_ADDRESS_T`

Convert text_t to ipv6_address_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ipv6_address_t : This object represents an IPv6 address present in the 1000:1001:CD10:0000:0000:89AB:4567:CDEF format.)

`Returns:` ipv6_address_t

`*TYPECAST_IPV6_SUBNET_AT`

Convert text_t to ipv6_subnet_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ipv6_subnet_at : Provides operations for the integral IPv6 subnet address value.)

`Returns:` ipv6_subnet_at

`*TYPECAST_IPV6_SUBNET_T`

Convert text_t to ipv6_subnet_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ipv6_subnet_t : This object represents an IPv6 subnet address present in the 1000:1001:CD10:0000:0000:89AB:4567:CDEF/64 format.)

`Returns:` ipv6_subnet_t

`*TYPECAST_IP_ADDRESS_AT`

Convert text_t to ip_address_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ip_address_at : Provides operations for the 32-bit integral IP address value.)

`Returns:` ip_address_at

`*TYPECAST_IP_ADDRESS_T`

Convert text_t to ip_address_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ip_address_t : Represents an IP address present in the 10.100.200.1 format.)

`Returns:` ip_address_t

`*TYPECAST_IP_OPTIONS_T`

Convert text_t to ip_options_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ip_options_t : IP protocol options)

`Returns:` ip_options_t

`*TYPECAST_IP_OPTIONS_TYPE_T`

Convert text_t to ip_options_type_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ip_options_type_t : IP Options Type)

`Returns:` ip_options_type_t

`*TYPECAST_IP_TOS_T`

Convert text_t to ip_tos_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ip_tos_t : Provides operations to TOS field in IP header.)

`Returns:` ip_tos_t

`*TYPECAST_LIST_T` (`char` sep)

Convert text_t to list_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (list_t : The character separator has to be provided when typecasting a textual context to list type. The current text mode has no effect on the character separator. For example if the current text mode is IGNORECASE and the separator is p then P will not be treated as a separator.)

`Parameters` (expressions not allowed) `:`

sep- Separator

`Returns:` list_t

`*TYPECAST_MAC_ADDRESS_AT`

Convert text_t to mac_address_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (mac_address_at : Provides operations for the 48-bit MAC address value.)

`Returns:` mac_address_at

`*TYPECAST_MAC_ADDRESS_T`

Convert text_t to mac_address_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (mac_address_t : Represents a MAC address present in the 12:34:56:78:9a:bc format.)

`Returns:` mac_address_t

`*TYPECAST_NUM_AT`

Convert text_t to num_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (num_at : Number Value)

`Returns:` num_at

`*TYPECAST_NUM_T` (num_format_e format)

Convert text_t to num_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (num_t : Treat the underlying text as a Number in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error.)

`Parameters` (expressions not allowed) `:`

format- Format

`Returns:` num_t

`*TYPECAST_NUM_T` (num_format_e format, num_at default_value)

Convert text_t to num_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (num_t : Treat the underlying text as a Number in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` num_t

`*TYPECAST_NVLIST_T` (`char` sep1, `char` sep2)

Convert text_t to nvlist_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (nvlist_t : Two character delimiters have to be provided when typecasting a Text object to a Name-Value List. The first delimited separates the name from the value. The second delimiter separates list items. For example typecast_nvlist_t('=', '&') handles a

URL query string. The Text Mode has no effect on the character delimiters. For example if the current text mode is IGNORECASE and a delimiter is p then P will not be treated as a delimiter.)

`Parameters` (expressions not allowed) `:`

sep1- delimiter1

sep2- delimiter2

`Returns:` nvlist_t

`*TYPECAST_NVLIST_T` (`char` sep1, `char` sep2, `char` quote)

Convert text_t to nvlist_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (nvlist_t : Two character delimiters and quote-character have to be provided when typecasting a Text object to a Name-Value List that supports quote-character. The first delimited separates the name from the value. The second delimiter separates list items. The third value specifies the quote character. For example typecast_nvlist_t('=', ';', "") handles a name-value list separated by semi-colons that allows quoting. The quote-character specifies that the value can occur within the quotes and the delimiters within the quote-characters should not be taken into account. The Text Mode has no effect on the character delimiters. For example if the current text mode is IGNORECASE and a delimiter is p then P will not be treated as a delimiter.)

`Parameters` (expressions not allowed) `:`

sep1- delimiter1

sep2- delimiter2

quote- quote-character.

`Returns:` nvlist_t

`*TYPECAST_PROTOCOL_BUFFER_T`

Convert text_t to protocol_buffer_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (protocol_buffer_t : gRPC Protocol Buffers interface)

`Returns:` protocol_buffer_t

`*TYPECAST_RADIUS_AVP_T`

Convert text_t to radius_avp_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (radius_avp_t : Operations that can be performed on the returned AVPs.

`Note:` An AVP can have multiple instances in a radius message. However, the system can access only the first 16 instances.

`Example:`

- To get the first value of AVP code 26 from a request, use: radius.REQ.AVP(26).VALUE(0).
- To get the fourth value of AVP code 26 from a request, use: radius.REQ.AVP(26).VALUE(3).

)

`Returns:` radius_avp_t

`*TYPECAST_RADIUS_AVP_VALUE_T`

Convert text_t to radius_avp_value_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (radius_avp_value_t : Provides operations to typecast RADIUS AVP value to Integer value or IP Address.)

`Returns:` radius_avp_value_t

`*TYPECAST_SEQ_TEXT_T`

Convert text_t to seq_text_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (seq_text_t : Represents the Text Sequence class.)

`Returns:` seq_text_t

`*TYPECAST_SERVICEPATH_T`

Convert text_t to servicepath_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (servicepath_t : Operations that can be performed on the service path.

`Example:`

- To get the name of the service path applicable to current subscriber, use: SUBSCRIBER.SERVICEPATH
- To determine If the service function is the next in the service path applicable to scubscriber, use: SUBSCRIBER.SERVICEPATH.IS_NEXT().

)

`Returns:` servicepath_t

`*TYPECAST_SIP_CALLID_HEADER_T`

Convert text_t to sip_callid_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_callid_header_t : This object provides operations for parsing the SIP callid header.)

`Returns:` sip_callid_header_t

`*TYPECAST_SIP_CONTENT_LENGTH_T`

Convert text_t to sip_content_length_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_content_length_t : The SIP.REQ.CONTENT_LENGTH or SIP.RES.CONTENT_LENGTH object can be treated as a SIP Header or as a Number. The numerical value for this object is derived from the value in the last instance of the Content-Length header.)

`Returns:` sip_content_length_t

`*TYPECAST_SIP_FROM_HEADER_T`

Convert text_t to sip_from_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_from_header_t : This object provides operations for parsing the SIP From header.)

`Returns:` sip_from_header_t

`*TYPECAST_SIP_HEADER_T` (text_t name)

Convert text_t to sip_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_header_t : When typecasting a Text object to SIP Header a header name must be provided.For example: SIP.REQ.HEADER("MyHdr").TYPECAST_SIP_HEADER_T("InHdr"))

`Parameters` (expressions not allowed) `:`

name- Header Name

`Returns:` sip_header_t

`*TYPECAST_SIP_HOSTNAME_T`

Convert text_t to sip_hostname_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_hostname_t : This object provides operations for parsing the SIP hostname as it appears at various places in the SIP protocol data. The format is abc.foo.com:5060.)

`Returns:` sip_hostname_t

`*TYPECAST_SIP_METHOD_T`

Convert text_t to sip_method_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_method_t : This object provides Text operations and SIP Request Method Enum operations on the SIP request method.)

`Returns:` sip_method_t

`*TYPECAST_SIP_TO_HEADER_T`

Convert text_t to sip_to_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_to_header_t : This object provides operations for parsing the SIP From header.)

`Returns:` sip_to_header_t

`*TYPECAST_SIP_URL_T`

Convert text_t to sip_url_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_url_t : SIP.REQ.URL provides operations for parsing and operating on the URL that is present in the first line of the SIP request header. The supported format is \[<protocol>://<hostname>\]<path>?<query>. The Text object backing a SIP URL object has the Text Mode set to URLENCODED by default.)

`Returns:` sip_url_t

`*TYPECAST_SIP_VERSION_T`

Convert text_t to sip_version_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_version_t : SIP.REQ.VERSION or SIP.RES.VERSION provide operations to extract SIP version information.)

`Returns:` sip_version_t

`*TYPECAST_SIP_VIA_HEADER_T`

Convert text_t to sip_via_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_via_header_t : This object provides operations for parsing the SIP Via header.)

`Returns:` sip_via_header_t

`*TYPECAST_SSLVPN_MODE_T`

Convert text_t to sslvpn_mode_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sslvpn_mode_t : This object provides Text operations and SSLVPN Mode Enum operations on the SSLVPN request method.)

`Returns:` sslvpn_mode_t

`*TYPECAST_SSL_TEXT_T` (text_t name)

Convert text_t to ssl_text_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ssl_text_t : Treat the underlying text object as SSL Text.)

`Parameters` (expressions not allowed) `:`

name- Name

`Returns:` ssl_text_t

`*TYPECAST_TCP_OPTIONS_T`

Convert text_t to tcp_options_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (tcp_options_t : TCP Protocol Options)

`Returns:` tcp_options_t

`*TYPECAST_TCP_OPTIONS_TYPE_T`

Convert text_t to tcp_options_type_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (tcp_options_type_t : TCP Protocol Options Type)

`Returns:` tcp_options_type_t

`*TYPECAST_TCP_REPEATER_OPTION_T`

Convert text_t to tcp_repeater_option_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (tcp_repeater_option_t : TCP Protocol Option : Repeater)

`Returns:` tcp_repeater_option_t

`*TYPECAST_TEXT_T`

Convert http_header_t to text_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (text_t : Designates any piece of text.)

`Returns:` text_t

`*TYPECAST_TIME_AT`

Convert text_t to time_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (time_at : Treats a number value as number of seconds since GMT Jan 1 1970 0h 0m 0s.)

`Returns:` time_at

`*TYPECAST_TIME_LOCAL_AT`

Convert text_t to time_local_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (time_local_at : Treats a number value as number of seconds since GMT Jan 1 1970 0h 0m 0s as adjsuted for the local time zone.)

`Returns:` time_local_at

`*TYPECAST_TIME_T`

Convert text_t to time_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (time_t : This object treats a Text object as a date string. The formats supported are

1\. RFC822 :: Sun, 06 Nov 1994 08:49:37 GMT 2\. RFC850 :: Sunday, 06-Nov-94 08:49:37 GMT 3\. ASCTIME :: Sun Nov 6 08:49:37 1994 4\. ASCTIME like :: Sun Nov 6 08:49:37 1994 5\. ASCTIME like :: Sun Nov 06 08:49:37 1994 6\. Http Set-Cookie Expiry date :: Sun, 06-Nov-1994 08:49:37 GMT)

`Returns:` time_t

`*TYPECAST_UNSIGNED_LONG_AT`

Convert text_t to unsigned_long_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_at : Unsigned Long(64bit) Value)

`Returns:` unsigned_long_at

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error.)

`Parameters` (expressions not allowed) `:`

format- Format

`Returns:` unsigned_long_t

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format, ip_address_at default_value)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` unsigned_long_t

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format, unsigned_long_at default_value)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX,

DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` unsigned_long_t

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format, num_at default_value)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` unsigned_long_t

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format, time_local_at default_value)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one

or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` unsigned_long_t

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format, time_at default_value)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` unsigned_long_t

`*TYPECAST_UNUM_TEXT_T`

Convert text_t to unum_text_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unum_text_t : Provides operations to treat the underlying OctectString as Binary String or unsigned long value .)

`Returns:` unum_text_t

`*TYPECAST_URL_CATEGORY_T`

Convert text_t to url_category_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (url_category_t : Retrieves URL category and attributes from an URL)

`Returns:` url_category_t

`*TYPECAST_VENDOR_SPEC_APPID_AVP_T`

Convert text_t to vendor_spec_appid_avp_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (vendor_spec_appid_avp_t : Retrieves AVPs that are nested in the grouped AVP Vendor-Specific-Application-Id (code 260). The nested AVPs are:

- Vendor-Id
- Auth-Application-Id
- Acct-Application-Id

For example, to retrieve the Auth-Application-Id AVP from the Vendor-Specific-Application-Id AVP:

- For requests: DIAMETER.REQ.VENDOR_SPECIFIC_APPLICATION_ID.AUTH_APPLICATION_ID
- For responses: DIAMETER.RES.VENDOR_SPECIFIC_APPLICATION_ID.AUTH_APPLICATION_ID

)

`Returns:` vendor_spec_appid_avp_t

`*TYPECAST_VENDOR_SPEC_RADIUS_AVP_T`

Convert text_t to vendor_spec_radius_avp_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (vendor_spec_radius_avp_t :

- Vendor-Id

To retrieve the Vendor-Id from the Vendor-Specific AVP:

- RADIUS.REQ.VENDOR_SPECIFIC.VENDORID

)

`Returns:` vendor_spec_radius_avp_t

`*UNQUOTE` (`char` c)

If selected text is quoted by character c, Remove character c from beginning and end.

For example: Say the selected text is / "foo xyz bar " /. Then on executing UNQUOTE("") the selected text will become /foo xyz bar / This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

c- Character

`Returns:` text_t

`*URLSET_MATCHES_ANY` (text_t urlset_name)

Results in Boolean TRUE value if and only if the Text matches any of the patterns that are specified in the urlset named by the string argument. The matching is case-insensitive for domains, but case-sensitive for paths. For example:

- HTTP.REQ.HOST.APPEND(HTTP.REQ.URL).URLSET_MATCHES_ANY("urlset_forbidden") returns true when the combined domain and URL matches any pattern in the urlset whose name is "urlset_forbidden".

`Parameters` (expressions not allowed) `:`

urlset_name- urlset name

`Returns:` bool_at

`*URL_CATEGORIZE` (`uint` min_reputation, `uint` max_reputation)

Returns the URL category for the supplied URL with the given minimum and maximum reputation score. Where a score of 5 is most risky and 1 is least risky. If either score is set to 0, that bound would be ignored. By specifying the reputation scores, the function will returned the category with the highest score (most risky) based on the bounds. If there was an error getting the category or if the URL is invalid then it will result in an Undef error. For example: HTTP.REQ.HOST.APPEND(HTTP.REQ.URL).URL_CATEGORIZE(0, 0) returns value when the combined domain and URL is looked up for the URL category with the highest reputation score (most risky).

`Parameters` (expressions not allowed) `:`

min_reputation- Minimum reputation score of URL category

max_reputation- Maximum reputation score of URL category

`Returns:` url_category_t

`*URL_RESERVED_CHARS_SAFE`

Converts URL reserved characters to corresponding '%XX' values and retains the rest. This is a read only operation.

```
Based on RFC3986, following are considered URL unreserved characters:

    Alpha-numeric characters: a-z, A-Z, 0-9

    Hyphen and underscore: "-", "_"

    Dot: "."

    Tilde: "~"
```

The rest are converted to %XX encoding, 'XX' is the hex-based representation of the input character. If the requirement is to encode all but URL safe characters, please consider using HTTP_URL_SAFE method.

`Returns:` text_t

`*VALUE` (`uint` lineno)

An HTTP header can have multiple occurrences. VALUE(0) will select the value in the last header line of the current type, VALUE(1) will select the value in the last but one header line and so on. The counting goes backward. Only the last 15 instances of a header are accessible. Therefore Instance Number cannot be greater than 14.

HTTP/1.1 200 OK\\r\\n MyHdr: abc\\r\\n Content-Length: 200\\r\\n MyHdr: def\\r\\n \\r\\n

For example: HTTP.RES.HEADER("MyHdr").VALUE(1) will return a Text object referring to "abc\\r\\n".

`Parameters` (expressions not allowed) `:`

lineno- Instance Number

`Returns:` text_t

`*XML_DECRYPT` (text_t certKeyName)

Decrypt the selected content, which was encrypted using the W3C XML Encryption standard.

`Parameters` (expressions not allowed) `:`

certKeyName- identifies the certkey object containing the RSA private key to be used to decrypt the bulk encryption key in the selected EncryptedData element.

`Returns:` text_t

`*XML_ENCRYPT` (text_t certKeyName, encrypt_method_e method)

Encrypt the selected cleartext using the W3C XML Encryption standard.

`Parameters` (expressions not allowed) `:`

certKeyName- identifies the certkey object containing an X.509 certificate with the RSA public key to be used to encrypt the generated bulk encryption key. Note that the certKey object need not, and usually will not, include the associated RSA private key.

method- specifies the bulk encryption method (rc4, des3, aes128, aes192, or aes256) used to encrypt the content.

`Returns:` text_t

`*XML_ENCRYPT` (text_t certKeyName, encrypt_method_e method, `uint` flags)

Encrypt the selected cleartext using the W3C XML Encryption standard.

`Parameters` (expressions not allowed) `:`

certKeyName- identifies the certkey object containing an X.509 certificate with the RSA public key to be used to encrypt the generated bulk encryption key. Note that the certKey object need not, and usually will not, include the associated RSA private key.

method- specifies the bulk encryption method (rc4, des3, aes128, aes192, or aes256) used to encrypt the content.

flags- optional bit mask to specify optional elements in the EncryptedData element. These are hints to tell the receiver what private key to use to decrypt the bulk encryption key, providing information from the certKey's X.509 certificate.

- 1 - include a KeyName element with the certKeyName;
- 2 - include a KeyValue element with the RSA public key from the certificate;
- 4 - include an X509IssuerSerial element with the certificate serial number and issuer DN;
- 8 - include an X509SubjectName element with the certificate subject DN;

- 16 - include an X509Certificate element with the entire certificate;

`Returns:` text_t

`*XPATH_HTML_WITH_MARKUP` (`xpath_str` xpathex)

Applies an XPath expression to the DOM for an HTML document and returns the selected node-set or string, including markup like element tags. node-sets are converted to strings using the standard XPath string conversion routine. The selected portion of the document can be used as the target for rewrite actions.

Examples: HTTP.REQ.BODY(1000).XPATH_HTML_WITH_MARKUP(xp%//md/head/title%) returns the <title> element in the document's <head> This can be used in a rewrite action to replace or delete the <title> element.

`Parameters` (expressions not allowed) `:`

xpathex- XPath Expression

`Returns:` text_t

`*XPATH_HTML` (`xpath_bool` xpathex)

Applies an XPath expression to the DOM for an HTML document and a boolean value.

Examples: HTTP.RES.BODY(1000).XPATH_HTML(xp%boolean(/md/head/meta)%) returns true if the <meta> element exists as a child of <head> element.

`Parameters` (expressions not allowed) `:`

xpathex- XPath Expression

`Returns:` bool_at

`*XPATH_HTML` (`xpath_double` xpathex)

Applies an XPath expression to the DOM for an HTML document and a double value.

Examples: HTTP.RES.BODY(1000).XPATH_HTML(xp%number(//video/@height)%) returns the numeric value of the height attribute of the first <video> element.

`Parameters` (expressions not allowed) `:`

xpathex- XPath Expression

`Returns:` double_at

`*XPATH_HTML` (`xpath_str` xpathex)

Applies an XPath expression to the DOM for an HTML document and returns the selected node-set or string. node-sets are converted to strings using the standard XPath string conversion routine.

Examples: HTTP.REQ.BODY(1000).XPATH_HTML(xp%//img/@src%) returns the string value of the src attribute of the first

HTTP_TRACKING_E

Provides the tracking type of the HTTP Request or Response. (Length, Fin, Chunk)

Enumerations

LENGTH

FIN

CHUNK

UNKNOWN_TRACKING

This topic lists the expressions that are provided by this class.

`EQ` (http_tracking_e t)

The result is Boolean TRUE if the tracking type of the HTTP request or response matches the input argument.

`Parameters` (expressions not allowed) `:`

t- Http Tracking Mechanism

`Returns:` bool_at

HTTP_URL_T

HTTP.REQ.URL provides operations for parsing and operating on the URL that is present in the first line of the HTTP request header. The supported format is \[<protocol>://<hostname>\]<path>?<query>. The Text object backing a HTTP URL object has the Text Mode set to URLENCODED by default.

This topic lists the expressions that are provided by this class.

`*Note` *: Expressions with the * symbol are inherited / promoted from text_t

`APPEND_QUERY_PARAMETER` (text_t name, text_t value)

Returns the URL string with a query parameter appended. This function appends query parameter after Converting URL unsafe characters into corresponding '%xx' values and retains the rest.

`Parameters` (expressions not allowed) `:`

name- query parameter name

value- query parameter value

`Returns:` http_url_t

`*HOSTNAME`

Operate as HTTP Host Name on the hostname present in the URL. Sets the text mode to case insensitive. It can not be used in HTTP response processing contexts.

`Returns:` http_hostname_t

`*PATH`

Operate as a / separated List on the path component of the URL. For example: If the URL is http://www.foo.com/a/b/c/bar.html?a=1 then operation will select /a/b/c/bar.html. HTTP.REQ.URL.PATH.GET(1) in the above example will select "a".

`Returns:` list_t

`*PATH_AND_QUERY`

Operate as Text on the portion of the URL following the hostname. For example: If the URL is http://www.foo.com/a/b/c/bar.html?a=1 then it will return /a/b/c/bar.html?a=1.

`Returns:` text_t

`*PROTOCOL`

Operate as Text on the protocol present in the URL. It can not be used in HTTP response processing contexts.

`Returns:` text_t

`*QUERY`

Operate as a Name-Value List (with delimiters = and &) on the query component of the URL.

`Returns:` nvlist_t

`*STRIP_SUFFIX`

Returns the URL with its suffix stripped. For Example: If the HTTP Request URL is /testsite/file5.html then it will return /testsite/file5 as output. If the HTTP Request URL is /testsite/file5 then it will return /testsite/file5 as output.

`Returns:` text_t

`*SUFFIX`

Operate as Text on the filename suffix present in the filename component of the URL. For example: If the PATH is /a/b/c/foo.bar.html then this operation will select md.

`Returns:` text_t

`*TYPECAST_TEXT_T`

Convert http_url_t to text_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (text_t : Designates any piece of text.)

`Returns:` text_t

`*AFTER_REGEX` (`re` regex)

Selects the text after the portion that matches the given regular expression argument. The first match is returned when multiple matches occur in the text. The match may occur anywhere within the text - if you wish to "anchor" this, use "\^" at the start of the regex and/or "$" at the end of the

regex. When the regular expression does not match the given string, a Text object of length of 0 is returned.

Example: HTTP.REQ.HEADER("etag").AFTER_REGEX(re/KX/) will select "DAPPER" from "KXDAPPER". This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

regex- Regular Expression

`Returns:` text_t

`*AFTER_STR_ANY` (text_t patset_name)

Selects the Text that is present after the first occurrence of any of the strings that are bound to the patset named by the string argument. If there is no match to any of the strings bound to the patset in the current Text object then the result Text object has 0 length. The patset cannot have strings longer than 255 characters. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` text_t

`*AFTER_STR` (text_t s)

Selects the Text that is present after the first occurrence of the string argument. If there is no match for the argument in the current Text then the result Text object has 0 length. The input string cannot be bigger than 255 characters. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*APPEND` (bool_at b)

Appends the given boolean's string representation to the current string.

`Parameters``:`

b- the boolean value to append.

`Returns:` text_t

`*APPEND` (double_at i)

Appends the given double's string representation to the current string.

`Parameters``:`

i- the double value to append.

`Returns:` text_t

`*APPEND` (ip_address_at addr)

Appends the given IPv4's string representation to the current string.

`Parameters``:`

addr- the IPv4 address to append.

`Returns:` text_t

`*APPEND` (num_at i)

Appends the given number's string representation to the current string.

`Parameters``:`

i- the number value to append.

`Returns:` text_t

`*APPEND` (time_local_at t)

Appends the given time's string representation to the current string.

`Parameters``:`

t- the time value to append.

`Returns:` text_t

`*APPEND` (time_at t)

Appends the given time's string representation to the current string.

`Parameters``:`

t- the time value to append.

`Returns:` text_t

`*APPEND` (unsigned_long_at i)

Appends the given unsigned long's string representation to the current string.

`Parameters``:`

i- the unsigned long value to append.

`Returns:` text_t

`*APPEND` (ipv6_address_at addr)

Appends the given IPv6's string representation to the current string.

`Parameters``:`

addr- the IPv6 address to append.

`Returns:` text_t

`*APPEND` (ipv6_subnet_at addr)

Appends the given IPv6 subnet's string representation to the current string.

`Parameters``:`

addr- the IPv6 subnet to append.

`Returns:` text_t

`*APPEND` (mac_address_at addr)

Appends the given MAC's string representation to the current string.

`Parameters``:`

addr- the MAC address to append.

`Returns:` text_t

`*APPEND` (text_t str)

Appends the given string to the current string.

`Parameters``:`

str- the string to append.

`Returns:` text_t

`*APPEND` (time_at t)

Appends the given time's string representation to the current string.

`Parameters``:`

t- the time value to append.

`Returns:` text_t

`*B64DECODE`

Decodes the selected text using base64 decoding.

For example, the string "TWFu" is converted to "Man"

`Returns:` text_t

`*B64ENCODE`

Encodes the selected text using base64 encoding.

For example, the string "Man" is converted to "TWFu"

`Returns:` text_t

`*BEFORE_REGEX` (`re` regex)

Selects the text before the portion that matches the given regular expression argument. The first match is returned when multiple matches occur in the text. The match may occur anywhere within the text - if you wish to "anchor" this, use "\^" at the start of the regex and/or "$" at the end of the regex. When the regular expression does not match the given string, a Text object of length of 0 is returned.

For example: HTTP.RES.HEADER("content-type").BEFORE_REGEX(re#/#) will select "text" from "text/plain". This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

regex- Regular Expression

`Returns:` text_t

`*BEFORE_STR_ANY` (text_t patset_name)

Selects the Text that is present before the first occurrence of any of the strings that are bound to the patset or datasetnamed by the string argument. If there is no match to any of the strings bound to the patset in the current Text object then the result Text object has 0 length. The patset cannot have strings longer than 255 characters. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` text_t

`*BEFORE_STR` (text_t s)

Selects the Text that is present before the first occurrence of the string argument. If there is no match for the argument in the current Text object then the result Text object has 0 length. The input string cannot be bigger than 255 characters. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*BETWEEN` (text_t start, text_t end)

Results in Boolean TRUE value if length of the Text object is greater than or equal to the sum of the Start and End argument lengths and if the prefix of the Text object matches the Start string argument and if the Suffix of the Text object matches the End string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

start- Start

end- End

`Returns:` bool_at

`*BIN_DECODE` (binary_encoding_e encoding)

Decode the encoded input into its original byte sequence. An incorrectly enooded input will result in an Undef error.

`Parameters` (expressions not allowed) `:`

encoding- specifies how the bytes are encoded.

`Returns:` text_t

`*BIN_ENCODE` (binary_encoding_e encoding)

Encode the input byte sequence. Note that BIN_ENCODE(hex_colons) is equivalent to BLOB_TO_HEX().

`Parameters` (expressions not allowed) `:`

encoding- specifies how the bytes are to be encoded.

`Returns:` text_t

`*BLOB_TO_HEX`

Convert to hexadecimal representation and select text.

For example, the byte string abc is converted to 61:62:63.

`Returns:` text_t

`*COMPARE` (text_t s)

Results in a Number Value which is the result of comparison of the input argument with the Text object. The result is greater than 0 if the Text object is lexicographically greater than the argument. The result is 0 if the Text object and the argument match. The result is less than 0 if the Text object is lexicographically lesser than the argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` num_at

`*CONTAINS_ANY` (text_t patset_name)

Results in Boolean TRUE value if the Text contains any of the strings that are bound to the patset or dataset named by the string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` bool_at

`*CONTAINS_INDEX` (text_t patset_name)

Returns the numerical index of the matching string, if the Text contains any of the strings that are bound to the patset or dataset named by the string argument. Returns 0 if there is no match. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` num_at

`*CONTAINS` (text_t s)

Results in Boolean TRUE value if the Text contains the string given in the argument. The input string cannot be bigger than 255 characters. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*CRC32`

Returns a 32-bit integer computed by applying a CRC (cyclic redundancy check) function to the selected text. This is the CRC function used by Ethernet, MPEG-2, PKZIP, GZIP, PNG, and many other applications. For example, the expression to compute the CRC value of the (first 1000 bytes of the) body of an HTTP request is: HTTP.REQ.BODY(1000).CRC32

`Returns:` num_at

`*DECODE_USING_TEXT_MODE`

Decodes the selected text using the currently configured text encoding methods like URLENCODED, BACKSLASH_ENCODED, PLUS_AS_SPACE, NOURLENCODED, NO_BACKSLASH_ENCODED and NO_PLUS_AS_SPACE. Text encoding methods are set using SET_TEXT_MODE method.

`Returns:` text_t

`*DECRYPT`

Decrypt the selected base64-encoded ciphertext using the configured encryptionParams.

`Returns:` text_t

`*DECRYPT` (binary_encoding_e in_encoding)

Decrypt the selected ciphertext using the configured encryptionParams.

`Parameters` (expressions not allowed) `:`

in_encoding- specifies how the input ciphertext is encoded. If the ciphertext is not encoded as specified, causes an Undef error.

`Returns:` text_t

`*DECRYPT` (text_t encryptionKey)

Decrypt the selected base64-encoded encrypted bytes using the configured encryption key.

`Parameters` (expressions not allowed) `:`

encryptionKey- identifies the encryptionKey object to provide the cipher method, mode, padding, key, encrypted format and optional initialization vector (IV).

`Returns:` text_t

`*DECRYPT` (text_t encryptionKey, binary_encoding_e in_encoding)

Decrypt the selected base64-encoded encrypted bytes using the configured encryption key.

`Parameters` (expressions not allowed) `:`

encryptionKey- identifies the encryptionKey object to provide the cipher method, mode, padding, key, encrypted format, and optional initialization vector (IV).

in_encoding- specifies how the input ciphertext is encoded. If the ciphertext is not encoded as specified, causes an Undef error.

`Returns:` text_t

`*DIGEST` (digest_method_e method)

Returns a byte sequence computed by applying the the specified message digest method to the selected text.

`Parameters` (expressions not allowed) `:`

method- digest method to apply to the input text

`Returns:` text_t

`*ENCRYPT`

Encrypt the selected plaintext bytes using the configured encryptionParams. The resulting ciphertext is base64-encoded.

`Returns:` text_t

`*ENCRYPT` (binary_encoding_e out_encoding)

Encrypt the selected plaintext bytes using the configured encryptionParams.

`Parameters` (expressions not allowed) `:`

out_encoding- specifies how the resulting ciphertext is encoded.

`Returns:` text_t

`*ENCRYPT` (text_t encryptionKey)

Encrypt the selected cleartext bytes using the configured encryption key.

`Parameters` (expressions not allowed) `:`

encryptionKey- identifies the encryptionKey object to provide the cipher method, mode, padding, key, encrypted format and optional initialization vector (IV).

`Returns:` text_t

`*ENCRYPT` (text_t encryptionKey, binary_encoding_e out_encoding)

Encrypt the selected cleartext bytes using the configured encryption key.

`Parameters` (expressions not allowed) `:`

encryptionKey- identifies the encryptionKey object to provide the cipher method, mode, padding, key, encrypted format and optional initialization vector (IV).

out_encoding- specifies how the resulting ciphertext is encoded.

`Returns:` text_t

`*ENDSWITH_ANY` (text_t patset_name)

Results in Boolean TRUE value if the Text ends with any of the strings that are bound to the patset or dataset named by the string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` bool_at

`*ENDSWITH_INDEX` (text_t patset_name)

Returns the numerical index of the matching string, if the Text ends with any of the strings that are bound to the patset or dataset named by the string argument. Returns 0 if there is no match. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` num_at

`*ENDSWITH` (text_t end)

Results in Boolean TRUE value if a suffix of the Text object matches the string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

end- String

`Returns:` bool_at

`*EQUALS_ANY` (text_t patset_name)

Results in Boolean TRUE value if the Text equals any of the strings that are bound to the patset or dataset named by the string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` bool_at

`*EQUALS_INDEX` (text_t patset_name)

Returns the numerical index of the matching string, if the Text equals any of the strings that are bound to the patset or dataset named by the string argument. Returns 0 if there is no match. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` num_at

`*EQ` (text_t s)

Results in Boolean TRUE value if the Text object matches the input argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*GET_SIGNED16` (`uint` n, endian_e endianness)

Get the 16-bit signed binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

endianness- Select little or big endian

`Returns:` num_at

`*GET_SIGNED32` (`uint` n, endian_e endianness)

Get the 32-bit signed binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

endianness- Select little or big endian

`Returns:` num_at

`*GET_SIGNED8` (`uint` n)

Get the 8-bit signed binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

`Returns:` num_at

`*GET_UNSIGNED16` (`uint` n, endian_e endianness)

Get the 16-bit unsigned binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

endianness- Select little or big endian

`Returns:` num_at

`*GET_UNSIGNED32` (`uint` n, endian_e endianness)

Get the 32-bit unsigned binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

endianness- Select little or big endian

`Returns:` unsigned_long_at

`*GET_UNSIGNED64` (`uint` n, endian_e endianness)

Get the 64-bit unsigned binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

endianness- Select little or big endian

`Returns:` unsigned_long_at

`*GET_UNSIGNED8` (`uint` n)

Get the 8-bit unsigned binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

`Returns:` num_at

`*GET_URLSET_METADATA` (text_t urlset_name)

Returns metadata value corresponding to pattern in the urlset. The matching is case-insensitive for domains, but case-sensitive for paths. If no pattern is matched within the urlset, the return value is a NULL string. For example:

- HTTP.REQ.HOST.APPEND(HTTP.REQ.URL).GET_URLSET_METADATA("urlset_forbidden") returns value when the combined domain and URL is looked up in the urlset whose name is "urlset_forbidden".

`Parameters` (expressions not allowed) `:`

urlset_name- urlset name

`Returns:` text_t

`*GE` (text_t s)

Results in Boolean TRUE value if the Text object is greater than or equal to the input argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*GRPC`

Interprets a text_t string as a Protocol Buffer (protocol_buffer_t type). Example: HTTP.REQ.BODY(1000).GRPC.STRING(1).EQ("bookname")

`Returns:` protocol_buffer_t

`*GT` (text_t s)

Results in Boolean TRUE value if the Text object is greater than the input argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*HASH`

Returns a positive 31 bit integer value computed by applying a proprietary NetScaler hash function to the selected text. This function is not case- sensitive and ignores whitespaces. For example, applying the HASH function to two strings "Ab c" and "abc" would produce the same value. This function should not be used for security purposes; use instead the DIGEST function with one of the standard digest methods.

`Returns:` num_at

`*HMAC` (text_t hmacKey)

Returns a byte sequence computed by applying the HMAC (Hash Message Authenticastion Code) function to the selected text using the configured HMAC key.

`Parameters` (expressions not allowed)`:`

hmacKey- indentifies the hmacKey object to provide the digest (hash) method and the key.

`Returns:` text_t

`*HMAC` (text_t hmacKey, binary_encoding_e out_encoding)

Returns a byte sequence computed by applying the HMAC (Hash Message Authenticastion Code) function to the selected text using the configured HMAC key .

`Parameters` (expressions not allowed)`:`

hmacKey- indentifies the hmacKey object to provide the digest (hash) method and the key.

out_encoding- specifies how the resulting HMAC is encoded.

`Returns:` text_t

`*HTML_XML_SAFE`

Apply XML safe transform and select text.

Converts '<', '>' and '&' in the input text to '<', '>' and '&' respectively; other characters in the input are not modified. This transform safeguards against XSS based attacks. This is a read only operation.

`Returns:` text_t

`*HTTP_HEADER_SAFE`

Apply Header safe transform and select text. Converts all new line ('\\n') characters present in the input text to '%0A' so that they can safely be used in HTTP headers. This transform safeguards against response-splitting attacks. This is a read only operation.

`Returns:` text_t

`*HTTP_URL_SAFE`

Apply URL safe transform and select text. Converts URL unsafe characters to corresponding '%xx' values and retains the rest. This is a read only operation.

```
Based on RFC2396, following are considered URL safe characters:

    Alpha-numeric characters: a-z, A-Z, 0-9

    Hyphen and underscore: "-", "_"

    Dot: "."

    Exclamation mark: "!"

    Tilde: "~"

    Asterix: "&ast;"

    Single quote: "'"
```

```
    Open and close parentheses: "(", ")"

    Semi-colon: ";"

    Colon: ":"

    At symbol: "@"

    Question mark: "?"

    Equals: "="

    Dollar: "$"

    Percent: "%"

    Ampersand: "&"

    Plus: "+"

    Comma: ","

    Forward slash: ".html"
```

The rest are converted to %XX encoding, 'XX' is the hex-based representation of the input character. If the requirement is to encode all but URL unreserved characters, please consider using URL_RESERVED_CHARS_SAFE method.

`Returns:` text_t

`*IS_BOOL_AT`

Results in Boolean TRUE value if the Text is of boolean type.

`Returns:` bool_at

`*IS_DOUBLE_AT`

Results in Boolean TRUE value if the Text is of double data type.

`Returns:` bool_at

`*IS_IPV6_AT`

Results in Boolean TRUE value if the Text is of IPv6 data type.

`Returns:` bool_at

`*IS_IPV6_SUBNET_AT`

Results in Boolean TRUE value if the Text is of IPv6 subnet data type.

`Returns:` bool_at

`*IS_IP_AT`

Results in Boolean TRUE value if the Text is of IPv4 data type.

`Returns:` bool_at

`*IS_MAC_ADDRESS_AT`

Results in Boolean TRUE value if the Text is of mac address data type.

`Returns:` bool_at

`*IS_NUM_AT`

Results in Boolean TRUE value if the Text is of number type.

`Returns:` bool_at

`*IS_NUM_AT` (num_format_e format)

Results in Boolean TRUE value if the Text is of number type with given input base.

`Parameters` (expressions not allowed) `:`

format- number format

`Returns:` bool_at

`*IS_STRINGMAP_KEY` (text_t string_map_name)

Returns true if the string that it operates on is present in the string map. Text mode IGNORECASE, NOIGNORECASE - controls whether key lookup in string map is case sensitive or not. For example:

- HTTP.REQ.URL.IS_STRINGMAP_KEY("url_stringmap") returns true if value of HTTP.REQ.URL is present as key in the string map whose name is "url_stringmap".

- HTTP.REQ.URL.SET_TEXT_MODE(IGNORECASE). IS_STRINGMAP_KEY("url_stringmap") returns true if value of HTTP.REQ.URL is present as key in the string map whose name is "url_stringmap". Key lookup in this case is done case-insensitively.

`Parameters` (expressions not allowed) `:`

string_map_name- identifies the string map.

`Returns:` bool_at

`*IS_TIME_AT`

Results in Boolean TRUE if the Text follows any of the standard time formats given below, otherwise false. Tue, 05 Nov 1994 08:12:31 GMT RFC822 Tuesday, 05-Nov-94 08:12:31 GMT RFC850 Tue Nov 4 08:12:31 1994 asctime

`Returns:` bool_at

`*IS_UNSIGNED_LONG_AT`

Results in Boolean TRUE value if the Text is of unsigned long data type.

`Returns:` bool_at

`*IS_UNSIGNED_LONG_AT` (num_format_e format)

Results in Boolean TRUE value if the Text is of unsigned long data type with given input base.

`Parameters` (expressions not allowed) `:`

format- number format

`Returns:` bool_at

`*JWT_VERIFY_CERTKEY` (text_t certkey_name)

Verifies the signature on the input JSON Web Token (JWT), using the RSA public key in the X.509 certificate in the specified certkey object. The token has the format HEADER.PAYLOAD.SIGNATURE where

- HEADER is a base64-encoded JSON structure indicating a signature algorithm and token type, e.g.'{"alg":"RS256","typ":"JWT"}'
- PAYLOAD is a base64-encoded JSON structure with asserted claims, e.g. '{"loggedInAs":"admin","iat":1422779638}'

- SIGNATURE is the base64-encoded bytes for the signature on HEADER.PAYLOAD.

Returns true if the signature is verified for the header and payload using the specified public key; false if the signature is not verified

`Parameters``:`

certkey_name- identifies the certkey object containing an X.509 certificate holding the RSA public key. Results in an Undef error if the certkey object does not exist or does not contain an X.509 certificate with an RSA public key, if the token is not correctly formatted, or if the verification operation cannot complete.

`Returns:` bool_at

`*JWT_VERIFY_XML` (text_t xml_pkey)

Verifies the signature on the input JSON Web Token (JWT), using the RSA public key supplied by the specified XML element. The token has the format HEADER.PAYLOAD.SIGNATURE where

- HEADER is a base64-encoded JSON structure indicating a signature algorithm and token type, e.g.'{"alg":"RS256","typ":"JWT"}'
- PAYLOAD is a base64-encoded JSON structure with asserted claims, e.g. '{"loggedInAs":"admin","iat":1422779638}'
- SIGNATURE is the base64-encoded bytes for the signature on HEADER.PAYLOAD.

Returns true if the signature is verified for the header and payload using the specified public key; false if the signature is not verified

`Parameters``:`

xml_pkey- an expression that supplies an <RSAKeyValue> element with the public key. Results in an Undef error if the XML element is invalid or does not correctly specify an RSA public key, if the token is not correctly formatted, or if the verification operation cannot complete.

`Returns:` bool_at

`*LENGTH`

Results in a Number Value that is the number of characters (not bytes) in the Text object.

`Returns:` num_at

`*LE` (text_t s)

Results in Boolean TRUE value if the Text object is less than or equal to the input argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*LOCATION_LONG`

Get the location qualifier from CLIENT.IP.SRC.LOCATION.GET(n) (ISO short name) and then convert it to human readable long name. This conversion is valid only for country names. Correct Country qualifier value (number) in GET(n) is left up to the user as qualifiers are user configurable. Expression example: CLIENT.IP.SRC.LOCATION.GET(1).LOCATION_LONG For example: Data from each expression CLIENT.IP.SRC.LOCATION: NA.US.California.SantaClara.*.* CLIENT.IP.SRC.LOCATION.GET(1): US CLIENT.IP.SRC.LOCATION.GET(1).LOCATION_LONG: United States

`Returns:` text_t

`*LT` (text_t s)

Results in Boolean TRUE value if the Text object is less than the input argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*MAP_STRING_DEFAULT_TO_KEY` (text_t string_map_name)

Returns the value corresponding to the key in the string map. This is similar to the MAP_STRING method, but if the key is not present then instead of returning a null string, it returns the key itself. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed)`:`

string_map_name- identifies the string map.

`Returns:` text_t

`*MAP_STRING` (text_t string_map_name)

Returns value corresponding to key in the string map. Key is the string that it is given as input. Text mode IGNORECASE, NOIGNORECASE - controls whether key lookup in string map is case sensitive or not. For example:

- HTTP.REQ.URL.MAP_STRING("url_stringmap") returns value when the value of HTTP.REQ.URL is used as key in the string map whose name is "url_stringmap".
- HTTP.REQ.URL.SET_TEXT_MODE(IGNORECASE). MAP_STRING("url_stringmap") returns value when the value of HTTP.REQ.URL is used as key in the string map whose name is "url_stringmap". Key lookup in this case is done case-insensitively.

`Parameters` (expressions not allowed) `:`

string_map_name- identifies the string map.

`Returns:` text_t

`*MARK_SAFE`

Mark the PIXL expression safe without applying any safe transform.

`Returns:` text_t

`*MAX` (text_t s)

Compares the string argument with the current string and returns the max string. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*MIN` (text_t s)

Compares the string argument with the current string and returns the min string. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*NE` (text_t s)

Results in Boolean TRUE value if the Text object is not equal to the input argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*NORMALIZE_URL`

Normalize URL. Normalizes a URL by doing "percent" decoding. See the description for URLENCODED in the SET_TEXT_MODE function. This performs the equivalent of SET_TEXT_MODE(URLENCODED).DECODE_USING_TEXT_MODE, except that it does not change the value of the current text mode.

`Returns:` text_t

`*PKEY_ENCRYPT_PEM_NO_PADDING` (text_t pem_pkey)

Encrypts the input text using the RSA public key provided by the PEM string and RSA_NO_PADDING padding method. The input text to be encrypted cannot be longer than the public key length minus 11 bytes for padding. For example, for a 1024-bit (128 byte) key, the input text cannot be longer than 128 - 11 = 117 bytes. An Undef error will occur if the input text is too long. A null input will also cause an Undef error. Returns the (unencoded binary) encrypted text, which is typically base-64 encoded for use in a message.

`Parameters``:`

pem_pkey- a text expression that supplies a RSA public key in the PEM format. If the text value is not a valid PEM RSA PUBLIC KEY encoding, an Undef error will occur. Example (a 1024-bit public key):

```
"-----BEGIN RSA PUBLIC KEY-----" +

"MIGJAoGBAKl5vgQEj73Kxp+9yn1v5gPR1pnc4oLM2a0kaWwBOsB6rzCIy6znwnvw" +

"CY1xRvQhRlJSAyJbloL7wZFIJ2FOR8Cz+8ZQWXU2syG+udi4EnWqLgFYowF9zK+o" +

"79az597eNPAjsHZ/C2oL/+6qY5a/f1z8bQPrHC4GpFfAEJhh/+NnAgMBAAE=" +
```

```
"-----END RSA PUBLIC KEY-----"
```

`Returns:` text_t

`*PKEY_ENCRYPT_PEM` (text_t pem_pkey)

Encrypts the input text using the RSA public key provided by the PEM string and the RSA_PKCS1_PADDING padding method. The input text to be encrypted cannot be longer than the public key length minus 11 bytes for padding. For example, for a 1024-bit (128 byte) key, the input text cannot be longer than 128 - 11 = 117 bytes. An Undef error will occur if the input text is too long. A null input will also cause an Undef error. Returns the (unencoded binary) encrypted text, which is typically base-64 encoded for use in a message.

`Parameters``:`

pem_pkey- a text expression that supplies a RSA public key in the PEM format. If the text value is not a valid PEM RSA PUBLIC KEY encoding, an Undef error will occur. Example (a 1024-bit public key):

```
"-----BEGIN RSA PUBLIC KEY-----" +

"MIGJAoGBAKl5vgQEj73Kxp+9yn1v5gPR1pnc4oLM2a0kaWwBOsB6rzCIy6znwnvw" +

"CY1xRvQhRlJSAyJbloL7wZFIJ2FOR8Cz+8ZQWXU2syG+udi4EnWqLgFYowF9zK+o" +

"79az597eNPAjsHZ/C2oL/+6qY5a/f1z8bQPrHC4GpFfAEJhh/+NnAgMBAAE=" +

"-----END RSA PUBLIC KEY-----"
```

`Returns:` text_t

`*PKEY_SIGN_CERTKEY` (text_t certkey_name)

Generates a binary digital signature using the SHA-256 message digest function and an RSA private key from the specified SSL certKey object.

`Parameters``:`

certkey_name- identifies the configured certKey object. Results in an Undef error if the certkey object does not exist or does not contain an RSA private key, or if the signing operation cannot complete.

`Returns:` text_t

`*PKEY_SIGN_XML` (text_t xml_pkey)

Generates a binary digital signature using the SHA-256 message digest function and an RSA private key from the specified XML element.

`Parameters``:`

xml_pkey- an expression that supplies an <RSAKeyValue> element with the private key. Example: <RSAKeyValue> <Modulus>qXm+BASPvcrGn73KfW/
mA9HWmdzigszZrSRpbAE6wHqvMIjLrOfCe/
AJjXFG9CFGUlIDIluWgvvBkUgnYU5HwLP7xlBZdTazIb652LgSdaouAVijAX3Mr6jv1rPn3t408COwdn8Lagv/
7qpjlr9/XPxtA+scLgakV8AQmGH/42c=</Modulus> <Exponent>AQAB</Exponent>"zNjysxcIJV/
J9cTpIgPp2/x1IXHT5GTH8OMuNad0qtRSLjU1QYUmmkm9QcJJAN+7h8FEXWGabySUzBrHj/
IEbw==" <DP>QavUDQLLQpnPJXtVAo6CYhxOMCd68mwTxYKKNLjmC0pd54SFHllTLPE1FZU5EjK6q3nCeijonpfH+XX
DP> <DQ>EiXOKouJzzXTQJC3TqomF7Uf81yQNxWumOqnd11kepXgyfMwyqMvLlAGEkNSEF/
Bz18R3Wv+MIZ/IC3nLBt2xQ==</DQ> <InverseQ>ocuCmz36CP+N2aGqxaU+BKD5+3RLgRq9LFhULEz2jKx0iV9r76jsAxn3sLcTYYO9eqRPy2cz74A
nw==</InverseQ> <D>fTBD773a3GzcmgVdfZlaBLpN1ux2mf5uUVrTUQf7eVFm9egm4/
tzC5A9zjC+I/oscwTH8epL3UfRLdtp05Q6pWfJBXEnGo0QmOFFBK4pLx/
5JJpPGZ69ovDFEVOUHyiCfKE/g97T4WX3us0nFe1272zwGlHarM1YYwvfeE08UdE=</D> </
RSAKeyValue> Results in an Undef error if the XML element is invalid or does not correctly specify an RSA private key, or if the signing operation cannot complete.

`Returns:` text_t

`*PKEY_VERIFY_CERTKEY` (text_t certkey_name, text_t signature)

Verifies if the input text matches the specified signature generated using the SHA-256 messge digest function and the RSA private key associated with the specified RSA public key in the X.509 certificate in the specified certKey object. Returns true if the signature is verified, false otherwise.

`Parameters``:`

certkey_name- identifies the certkey object containing an X.509 certificate holding the RSA public key.

signature- the binary signature. Results in an Undef error if the certkey object does not exist or does not contain an X.509 certificate with an RSA public key, or if the verification operation cannot complete.

`Returns:` bool_at

`*PKEY_VERIFY_XML` (text_t xml_pkey, text_t signature)

Verifies if the input text matches the specified signature generated using the SHA-256 messge digest function and the RSA private key associated with the RSA public key supplied by the specified XML element. Returns true if the signature is verified, false otherwise.

`Parameters``:`

xml_pkey- an expression that supplies an <RSAKeyVAlue> element with the public key. Example: <RSAKeyValue> <Modulus>qXm+BASPvcrGn73KfW/mA9HWmdzigszZrSRpbAE6wHqvMIjLrOfCe/AJjXFG9CFGUlIDIluWgvvBkUgnYU5HwLP7xlBZdTazIb652LgSdaouAVijAX3Mr6jv1rPn3t408COwdn8Lagv/7qpjlr9/XPxtA+scLgakV8AQmGH/42c=</Modulus> <Exponent>AQAB</Exponent> </RSAKeyValue>

signature- the binary signature. Results in an Undef error if the XML element is invalid or does not correctly specify an RSA public key, or if the verification operation cannot complete.

`Returns:` bool_at

`*PREFIX` (`char` c, `uint` i)

Select a prefix of the Text. The selected prefix is the longest prefix that has at most Count (2nd argument) occurrences of character in the 1st argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

c- Character

i- Count

`Returns:` text_t

`*PREFIX` (`uint` i)

Select a prefix of the Text. The length of the prefix is equal to the number in the argument. If there aren't enough characters in the Text object then the entire Text is selected.

`Parameters``:`

i- Prefix Length

`Returns:` text_t

`*REGEX_MATCH` (`re` regex)

Returns TRUE if and only if the text contains at least one match of the regular expression argument. The match may occur anywhere within the text - if you wish to "anchor" this, use "\^" at the start of the regex and/or "$" at the end of the regex.

The regular expression has to be of the format: `re<delimiter>regular expression<same delimiter>`

The regular expression cannot be bigger than 1499 characters.

The regular expression should be acceptable by the PCRE regular expression library. Look at http://www.pcre.org/pcre.txt for documentation on the regular expression syntax. In particular, look at the pcrepattern man page.

There are some differences in the allowed syntax w.r.t PCRE syntax. Backreferences are not allowed. It is recommended not to use recursive regular expressions. The dot metacharacter matches newlines also. Unicode is not supported. SET_TEXT_MODE(IGNORECASE) overrides the (?i) internal option specified in the regular expression.

The PCRE library configuration can be seen in the system log, after executing 'nsapimgr -B" call ns_pixl_regex_show_config()"' at the shell prompt.

Some examples:

- HTTP.REQ.HOSTNAME.REGEX_MATCH(re/\[\[:alpha:\]\]+(abc){2,3}/)
- HTTP.REQ.URL.SET_TEXT_MODE(URLENCODED).REGEX_MATCH(re#(a*b+c*)#)
- HTTP.REQ.URL.REGEX_MATCH(re/a(?i)b/) matches ab and aB
- HTTP.REQ.URL.SET_TEXT_MODE(IGNORECASE).REGEX_MATCH(re/ab/) matches ab, aB, Ab and AB
- HTTP.REQ.BODY.REGEX_MATCH(re/(?ixm) (\^ab (.*) cd$) /) does a case-insensitive, multiline match where the dot metacharacter matches newline also. The regex itself can contain whitespace which will be ignored during the matching (x - extended regex).

This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

regex- Regular Expression

`Returns:` bool_at

`*REGEX_REPLACE` (`re` regex, text_t replacement, replacemode_e mode)

Selects the text that matches the given regular expression argument and replaces it with the the text given in the second argument. The third argument specifies whether the first match is only replaced when multiple matches occur in the text or all matches are replaced. The match may occur anywhere within the text - if you wish to "anchor" this, use "\^" at the start of the regex and/or "$" at the end of the regex. When the regular expression does not match the given string then the same string is returned.

For example: HTTP.RES.BODY(999).REGEX_REPLACE(re!\\bpassword:\\s*\\b!, "password: ***", ALL) will replace all occurrences of "password:" with "password: ***" This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

regex- Regular Expression

replacement- String to replace the match

mode- Mode of replacement

`Returns:` text_t

`*REGEX_SELECT` (`re` regex)

Selects the text that matches the given regular expression argument. The first match is returned when multiple matches occur in the text. The match may occur anywhere within the text - if you wish to "anchor" this, use "\^" at the start of the regex and/or "$" at the end of the regex. When the regular expression does not match the given string, a Text object of length of 0 is returned.

For example: HTTP.REQ.HEADER("via").REGEX_SELECT(re!NS-CACHE-\\d\\.\\d:\\s*\\d{1,3}!) will select "NS-CACHE-7.0: 70" This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

regex- Regular Expression

`Returns:` text_t

`*REPEAT` (`uint` i)

Produces a string which contains 'i' sequential copies of the input string.

`Parameters``:`

i- the number of times to repeat the string (0 or more)

`Returns:` text_t

`*SET_CHAR_SET` (charset_e charset)

Set the character set to use for subsequent functions that use text.

`Parameters` (expressions not allowed) `:`

charset- Character Set

`Returns:` http_url_t

`*SET_TEXT_MODE` (textmode_e mode)

The mode setting of a Text object controls the behavior of many Text operations. The Text mode settings may also control the behavior of some operations in objects (like List) that build upon the Text object. IGNORECASE, NOIGNORECASE - controls whether string comparison is case sensitive or not. URLENCODED - If set then all Text operations are carried out after translating all %HH or %uHHHH encodings in the underlying byte stream. 1. %HH will be translated to the character Y where HH denotes the ascii value of character Y in hexadecimal. For example, the encoded text "http%3a/.html" will be decoded to "http:/.html" 2. %uWWHH will be translated to the character sequence YZ where WW denotes the ascii value of character Y in hexadecimal and HH denotes the ascii value of character Z in hexadecimal. For example, the encoded text "http%u3a2f.html" and "http%u003a/.html" will both be decoded to"http:/.html" NOURLENCODED - Indicates that no percent encodings are present in the Text object. No percent decoding will be performed on the Text object. PLUS_AS_SPACE - If set then all Text operations are carried out after converting occurrences of the plus character to whitespace. For example, the text "hello+world" will be decoded to "hello world" NO_PLUS_AS_SPACE - If set, then the plus character will not be converted to whitespace in the Text object. BACKSLASH_ENCODED - If set, then all Text operations are carried out after performing the following operations: 1. \\XXX will be translated to the character Y where XXX denotes the ascii value of character Y in octal. The valid range of octal values for this type of encoding is \\0 to \\377. For example, the encoded text "http\

\72/.html" and "http\\072/.html" will both be decoded to "http:/.html" 2. \\xHH will be translated to the character Y where HH denotes the ascii value of character Y in hexadecimal. For example, the encoded text "http\\x3a/.html" will be decoded to "http:/.html" 3. \\\\uWWXX will be translated to the character sequence YZ where WW denotes the ascii value of character Y in hexadecimal and XX denotes the ascii value of character Z in hexadecimal. For example, the encoded text "http%u3a2f.html" and "http%u003a/.html" will both be decoded to"http:/.html" 4. Occurences of "\ \b", "\\n", "\\t", "\\f" and "\\r" are translated to the corresponding ascii characters. NO_BACKSLASH_ENCODED - If set, then backslash decoding will not be performed on the Text object. BAD_ENCODE_RAISE_UNDEF - If set, then UNDEF is raised if either the URLENCODED or BACKSLASH_ENCODED mode is set and a bad encoding corresponding to the specified encoding mode is encountered. NO_BAD_ENCODE_RAISE_UNDEF - If set, then UNDEF will not be raised when a bad encoding is encountered in the Text object. The Text operations operate on characters (as opposed to operating on bytes). By default a single byte represents a character using the ASCII encoding. But if URLENCODED mode is set then 3 bytes may represent a character. A PREFIX(3) operation will select the first 3 characters in the Text object. That means it may select up to 9 bytes for URLENCODED Text object. In the case of multibyte decodings as a result of %uXXXX or \\\\uXXXX, Text operations which attempt to treat the multiple decoded bytes as distinct characters are not allowed.

`Parameters` (expressions not allowed) `:`

mode- Text Mode

`Returns:` http_url_t

`*SKIP` (`char` c, `uint` i)

Select the Text after skipping over a prefix of the current Text. The skipped over prefix is the longest prefix that has at most Count (2nd argument) occurrences of character in the 1st argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

c- Character

i- Count

`Returns:` text_t

`*SKIP` (`uint` i)

Select the Text after skipping over a prefix in the current Text. The length of the prefix is equal to the number in the argument. If there aren't enough characters in the Text object then the entire Text is skipped over.

`Parameters` (expressions not allowed) `:`

i- Prefix Length

`Returns:` text_t

`*STARTSWITH_ANY` (text_t patset_name)

Results in Boolean TRUE value if the Text starts with any of the strings that are bound to the patset or dataset named by the string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` bool_at

`*STARTSWITH_INDEX` (text_t patset_name)

Returns the numerical index of the matching string, if the Text starts with any of the strings that are bound to the patset or dataset named by the string argument. Returns 0 if there is no match. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` num_at

`*STARTSWITH` (text_t start)

Results in Boolean TRUE value if a prefix of the Text object matches the string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

start- String

`Returns:` bool_at

`*STRIP_CHARS` (text_t s)

From the selected text remove the characters specified in the string.

For example: Say the selected text is / "foo.xyz=bar" /. Then on executing STRIP_CHARS('.=') or STRIP_CHARS('..=') the selected text will become /fooxyzbar /. Note that repeating character has same effect as it would be if it present only once. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*STRIP_END_CHARS` (text_t s)

Selects the Text after stripping off characters in the end of the current Text object.

For example: Say the selected text is / "foo.xyz=bar" /. Then on executing STRIP_END_CHARS('ar') the selected text will become /foo.xyz=b /. Note that repeating character has same effect as it would be if it present only once. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*STRIP_END_WS`

Selects the Text after stripping off white space in the end of the current Text object.

`Returns:` text_t

`*STRIP_START_CHARS` (text_t s)

Selects the Text after stripping off characters in the beginning of the current Text object.

For example: Say the selected text is / "foo.xyz=bar" /. Then on executing STRIP_START_CHARS('of') the selected text will become /.xyz=bar /. Note that repeating character has same effect as it would be if it present only once. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*STRIP_START_WS`

Selects the Text after stripping off white space in the beginning of the current Text object.

`Returns:` text_t

`*SUBSTR_ANY` (text_t patset_name)

Select any one sub-string that matches any string in the given patset or dataset. The patset cannot have strings longer than 255 characters. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` text_t

`*SUBSTR` (`uint` start, `uint` len)

Select the Text object of the given length at the given offset. Offset it 0 based. If there aren't enough characters after the offset then all the remaining characters are selected.

`Parameters``:`

start- Offset

len- Length

`Returns:` text_t

`*SUBSTR` (text_t s)

Select the first Text object that matches the input string argument. The input string cannot be bigger than 255 characters. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*SUFFIX` (`char` c, `uint` i)

Select a suffix of the Text. The selected suffix is the longest possible suffix containing at most Count (2nd arg) occurrences of the character in the 1st argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

c- Character

i- Count

`Returns:` text_t

`*SUFFIX` (`uint` i)

Select a suffix of the Text. The length of the suffix is equal to the number in the argument. If there aren't enough characters in the Text object then the entire Text is selected.

`Parameters``:`

i- Suffix Length

`Returns:` text_t

`*TO_LOWER`

Converts the selected text to lower case.

For example, the string "ABCd" is converted to "abcd"

`Returns:` text_t

`*TO_UPPER`

Converts the selected text to upper case.

For example, the string "abcD" is converted to "ABCD"

`Returns:` text_t

`*TRUNCATE` (`char` c, `uint` i)

Select the Text after truncating a suffix from the current Text object. The truncated suffix is the longest possible suffix containing at most Count (2nd arg) occurrences of the character in the 1st argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

c- Character

i- Count

`Returns:` text_t

`*TRUNCATE` (`uint` i)

Select the Text after truncating a suffix of the Text. The length of the suffix truncated is equal to the number in the argument. If there aren't enough characters in the Text then then all the characters are truncated.

`Parameters``:`

i- Suffix Length

`Returns:` text_t

`*TYPECAST_AVP_T`

Convert text_t to avp_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (avp_t : Operations that can be performed on the returned AVPs.

`Note:` An AVP can have multiple instances in a Diameter message. However, the system can access only the first 16 instances.

`Example:`

- To get the first value of AVP code 266 from a request, use: DIAMETER.REQ.AVP(266).VALUE(0).
- To get the fourth value of AVP code 266 from a request, use: DIAMETER.REQ.AVP(266).VALUE(3).
- To check if AVP code 1000 in the response has the vendor-specific bit set, use: DIAMETER.RES.AVP(1000).IS_VENDOR_SPECIFIC.

)

`Returns:` avp_t

`*TYPECAST_AVP_UNUM_T`

Convert text_t to avp_unum_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (avp_unum_t : In Diameter AVP based expressions can be written as DIAMETER.REQ.AVP(<avpcode>). For example Auth-Application-Id AVP (AVP code 258) can be extracted as DIAMETER.REQ.AVP(258) For few of the important AVPs we provide aliases. For example this AVP based expression can also be written as DIAMETER.REQ.AUTH_APPLICATION_ID. This expression returns either a object of class avp_t or returns a numerical value (object of class unsigned_long_at). The numerical value for this object is derived from the value in first instance of the AVP.)

`Returns:` avp_unum_t

`*TYPECAST_BOOL_AT`

Convert text_t to bool_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (bool_at : Boolean Operations)

`Returns:` bool_at

`*TYPECAST_COOKIE_T`

Convert text_t to cookie_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (cookie_t : The HTTP Cookie type provides operations for a cookie as it appears in the Set-Cookie and Set-Cookie2 header. In this type the Name-Value List operations are also available. The first delimiter is = and the element delimiter is ;. Multiple consecutive ; are treated as one. (Same as applying the method IGNORE_EMPTY_ELEMENTS on a Name-Value List.) You can use the Name-value List operations to access cookie attributes. The name comparison for all list operations is case insensitive. In this type Text operations are also available. Each cookie begins with a COOKIE_NAME=COOKIE_VALUE pair followed by zero or more semi-colon separated attribute-value pairs. If an attribute appears more than once in a cookie, the value associated with the first appearance of the attribute is returned.

Format Cookie: Cookie1=Value;Version=decimal;Value;Domain=Value;Path=Value)

`Returns:` cookie_t

`*TYPECAST_DIAMETER_FLAG_T`

Convert text_t to diameter_flag_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (diameter_flag_t : Provides operation to treat the underlying 1 byte as set of bit flags. then set/unset/test/reset_all operations can be done on flag)

`Returns:` diameter_flag_t

`*TYPECAST_DNS_DOMAINNAME_T`

Convert text_t to dns_domainname_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (dns_domainname_t : This object provides operations for parsing the DNS domain name as it appears at various places in the DNS data. The format is abc.foo.com.)

`Returns:` dns_domainname_t

`*TYPECAST_DNS_FLAG_T`

Convert text_t to dns_flag_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (dns_flag_t : Provides operations to test/set/unset a flag in dns header.)

`Returns:` dns_flag_t

`*TYPECAST_DOUBLE_AT`

Convert text_t to double_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_at : Double Value)

`Returns:` double_at

`*TYPECAST_DOUBLE_T` (double_format_e format)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error.)

`Parameters` (expressions not allowed) `:`

format- Format

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, double_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, ip_address_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, num_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one

or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, time_local_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, time_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, unsigned_long_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_HTTP_CACHE_CONTROL_T`

Convert text_t to http_cache_control_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_cache_control_t : This object provides for the ability to work on HTTP Cache-Control headers. The name comparison for all list operations is case insensitive.)

`Returns:` http_cache_control_t

`*TYPECAST_HTTP_CONTENT_LENGTH_T`

Convert text_t to http_content_length_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_content_length_t : The HTTP.REQ.CONTENT_LENGTH or HTTP.RES.CONTENT_LENGTH object can be treated as a HTTP Header or as a Number. The numerical value for this object is derived from the value in the last instance of the Content-Length header.)

`Returns:` http_content_length_t

`*TYPECAST_HTTP_COOKIE_T`

Convert text_t to http_cookie_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_cookie_t : This object provides operations for parsing

the HTTP cookie header. The name-value pair is derived from the value in the last instance of Cookie header. The format is Cookie : name0=value0; name1=value1; An HTTP Cookie header can have multiple occurrences. COUNT will return a Number containing how many headers of the current type exist. The name comparison for all list operations is case insensitive. The system does not keep track of more than 15 HTTP headers. The result will be undefined if there are more than 15 instances of the header.)

`Returns:` http_cookie_t

`*TYPECAST_HTTP_DATE_T`

Convert text_t to http_date_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_date_t : The HTTP.REQ.DATE or HTTP.RES.DATE object can be treated as a HTTP header or a Time object. The Time value is derived from the value in the last instance of the Date header. The date formats supported are RFC 822 (updated by RFC 1123), RFC 1036 (obsoletes RFC850) and ANSI C asctime() formats.)

`Returns:` http_date_t

`*TYPECAST_HTTP_HEADER_T` (text_t name)

Convert text_t to http_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_header_t : When typecasting a Text object to HTTP Header a header name must be provided.For example: HTTP.REQ.HEADER("MyHdr").TYPECAST_HTTP_HEADER_T("InHdr"))

`Parameters` (expressions not allowed) `:`

name- Header Name

`Returns:` http_header_t

`*TYPECAST_HTTP_HOSTNAME_T`

Convert text_t to http_hostname_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_hostname_t : This object provides operations for parsing the HTTP hostname as it appears at various places in the HTTP protocol data. The format is abc.foo.com:8080.)

`Returns:` http_hostname_t

`*TYPECAST_HTTP_METHOD_T`

Convert text_t to http_method_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_method_t : This object provides Text operations and HTTP Request Method Enum operations on the HTTP request method.)

`Returns:` http_method_t

`*TYPECAST_HTTP_SET_COOKIE_T`

Convert text_t to http_set_cookie_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_set_cookie_t : HTTP.RES.SET_COOKIE provides operations for parsing and operating on the SET-COOKIE header that is present in the HTTP response. HTTP Set-Cookie header supports Text and HTTP Header operations. For most Text operations the value in the last Set-Cookie header is selected. HTTP Set-Cookie header also supports special operations to extract cookies from the response. It is assumed that there will be only one cookie in a Set-Cookie header.)

`Returns:` http_set_cookie_t

`*TYPECAST_HTTP_URL_T`

Convert text_t to http_url_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_url_t : HTTP.REQ.URL provides operations for parsing and operating on the URL that is present in the first line of the HTTP request header. The supported format is \[<protocol>://<hostname>\]<path>?<query>. The Text object backing a HTTP URL object has the Text Mode set to URLENCODED by default.)

`Returns:` http_url_t

`*TYPECAST_HTTP_VERSION_T`

Convert text_t to http_version_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_version_t : HTTP.REQ.VERSION or HTTP.RES.VERSION provide operations to extract HTTP version information.)

`Returns:` http_version_t

`*TYPECAST_IPV6_ADDRESS_AT`

Convert text_t to ipv6_address_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ipv6_address_at : Provides operations for the 128-bit IPv6 address value. Some general information regarding IPv6 expressions: IPv6 PIXL expressions can be combined with other PIXL expressions using the '+' operator. The output is expected to be

the concatenation of the string representations of the individual PIXL expressions. No other operator other than '+' is expected to work when any of the operands is an IPv6 PIXL expression. Also, IPv6 PIXL expressions can be combined with any other type of PIXL expression except a PIXL expression that produces a bool result. In other words, if A and/or B are two IPv6 addresses, A+B should result in the string AB. When one of A or B is an IPv6 address, the other can only be a number or a string and not a boolean. Further, when A and/or B is an IPv6 address, the only operator allowed between them is '+'.

Example: Let the client source IPv6 address be ABCD:1234::ABCD. Let the server destination IPv4 address be 10.100.10.100. Then the expression CLIENT.IPV6.SRC + SERVER.IP.DST should produce the output "ABCD:1234::ABCD10.100.10.100". Similarly, CLIENT.IPV6.SRC + 5 should produce the result ABCD:1234::ABCD5)

`Returns:` ipv6_address_at

`*TYPECAST_IPV6_ADDRESS_T`

Convert text_t to ipv6_address_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ipv6_address_t : This object represents an IPv6 address present in the 1000:1001:CD10:0000:0000:89AB:4567:CDEF format.)

`Returns:` ipv6_address_t

`*TYPECAST_IPV6_SUBNET_AT`

Convert text_t to ipv6_subnet_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ipv6_subnet_at : Provides operations for the integral IPv6 subnet address value.)

`Returns:` ipv6_subnet_at

`*TYPECAST_IPV6_SUBNET_T`

Convert text_t to ipv6_subnet_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ipv6_subnet_t : This object represents an IPv6 subnet address present in the 1000:1001:CD10:0000:0000:89AB:4567:CDEF/64 format.)

`Returns:` ipv6_subnet_t

`*TYPECAST_IP_ADDRESS_AT`

Convert text_t to ip_address_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ip_address_at : Provides operations for the 32-bit integral IP address value.)

`Returns:` ip_address_at

`*TYPECAST_IP_ADDRESS_T`

Convert text_t to ip_address_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ip_address_t : Represents an IP address present in the 10.100.200.1 format.)

`Returns:` ip_address_t

`*TYPECAST_IP_OPTIONS_T`

Convert text_t to ip_options_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ip_options_t : IP protocol options)

`Returns:` ip_options_t

`*TYPECAST_IP_OPTIONS_TYPE_T`

Convert text_t to ip_options_type_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ip_options_type_t : IP Options Type)

`Returns:` ip_options_type_t

`*TYPECAST_IP_TOS_T`

Convert text_t to ip_tos_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ip_tos_t : Provides operations to TOS field in IP header.)

`Returns:` ip_tos_t

`*TYPECAST_LIST_T` (`char` sep)

Convert text_t to list_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (list_t : The character separator has to be provided when typecasting a textual context to list type. The current text mode has no effect on the character separator. For example if the current text mode is IGNORECASE and the separator is p then P will not be treated as a separator.)

`Parameters` (expressions not allowed) `:`

sep- Separator

`Returns:` list_t

`*TYPECAST_MAC_ADDRESS_AT`

Convert text_t to mac_address_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (mac_address_at : Provides operations for the 48-bit MAC address value.)

`Returns:` mac_address_at

`*TYPECAST_MAC_ADDRESS_T`

Convert text_t to mac_address_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (mac_address_t : Represents a MAC address present in the 12:34:56:78:9a:bc format.)

`Returns:` mac_address_t

`*TYPECAST_NUM_AT`

Convert text_t to num_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (num_at : Number Value)

`Returns:` num_at

`*TYPECAST_NUM_T` (num_format_e format)

Convert text_t to num_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (num_t : Treat the underlying text as a Number in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error.)

`Parameters` (expressions not allowed) `:`

format- Format

`Returns:` num_t

`*TYPECAST_NUM_T` (num_format_e format, num_at default_value)

Convert text_t to num_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (num_t : Treat the underlying text as a Number in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` num_t

`*TYPECAST_NVLIST_T` (`char` sep1, `char` sep2)

Convert text_t to nvlist_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (nvlist_t : Two character delimiters have to be provided when typecasting a Text object to a Name-Value List. The first delimited separates the name from the value. The second delimiter separates list items. For example typecast_nvlist_t('=', '&') handles a URL query string. The Text Mode has no effect on the character delimiters. For example if the current text mode is IGNORECASE and a delimiter is p then P will not be treated as a delimiter.)

`Parameters` (expressions not allowed) `:`

sep1- delimiter1

sep2- delimiter2

`Returns:` nvlist_t

`*TYPECAST_NVLIST_T` (`char` sep1, `char` sep2, `char` quote)

Convert text_t to nvlist_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (nvlist_t : Two character delimiters and quote-character have to be provided when typecasting a Text object to a Name-Value List that supports quote-character. The first delimited separates the name from the value. The second delimiter separates list items. The third value specifies the quote character. For example typecast_nvlist_t('=', ';', "") handles a name-value list separated by semi-colons that allows quoting. The quote-character specifies that the

value can occur within the quotes and the delimiters within the quote-characters should not be taken into account. The Text Mode has no effect on the character delimiters. For example if the current text mode is IGNORECASE and a delimiter is p then P will not be treated as a delimiter.)

`Parameters` (expressions not allowed) `:`

sep1- delimiter1

sep2- delimiter2

quote- quote-character.

`Returns:` nvlist_t

`*TYPECAST_PROTOCOL_BUFFER_T`

Convert text_t to protocol_buffer_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (protocol_buffer_t : gRPC Protocol Buffers interface)

`Returns:` protocol_buffer_t

`*TYPECAST_RADIUS_AVP_T`

Convert text_t to radius_avp_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (radius_avp_t : Operations that can be performed on the returned AVPs.

`Note:` An AVP can have multiple instances in a radius message. However, the system can access only the first 16 instances.

`Example:`

- To get the first value of AVP code 26 from a request, use: radius.REQ.AVP(26).VALUE(0).
- To get the fourth value of AVP code 26 from a request, use: radius.REQ.AVP(26).VALUE(3).

)

`Returns:` radius_avp_t

`*TYPECAST_RADIUS_AVP_VALUE_T`

Convert text_t to radius_avp_value_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (radius_avp_value_t : Provides operations to typecast RADIUS AVP value to Integer value or IP Address.)

`Returns:` radius_avp_value_t

`*TYPECAST_SEQ_TEXT_T`

Convert text_t to seq_text_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (seq_text_t : Represents the Text Sequence class.)

`Returns:` seq_text_t

`*TYPECAST_SERVICEPATH_T`

Convert text_t to servicepath_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (servicepath_t : Operations that can be performed on the service path.

`Example:`

- To get the name of the service path applicable to current subscriber, use: SUBSCRIBER.SERVICEPATH
- To determine If the service function is the next in the service path applicable to scubscriber, use: SUBSCRIBER.SERVICEPATH.IS_NEXT().

)

`Returns:` servicepath_t

`*TYPECAST_SIP_CALLID_HEADER_T`

Convert text_t to sip_callid_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_callid_header_t : This object provides operations for parsing the SIP callid header.)

`Returns:` sip_callid_header_t

`*TYPECAST_SIP_CONTENT_LENGTH_T`

Convert text_t to sip_content_length_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_content_length_t : The SIP.REQ.CONTENT_LENGTH or SIP.RES.CONTENT_LENGTH object can be treated as a SIP Header or as a Number. The numerical value for this object is derived from the value in the last instance of the Content-Length header.)

`Returns:` sip_content_length_t

`*TYPECAST_SIP_FROM_HEADER_T`

Convert text_t to sip_from_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_from_header_t : This object provides operations for parsing the SIP From header.)

`Returns:` sip_from_header_t

`*TYPECAST_SIP_HEADER_T` (text_t name)

Convert text_t to sip_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_header_t : When typecasting a Text object to SIP Header a header name must be provided.For example: SIP.REQ.HEADER("MyHdr").TYPECAST_SIP_HEADER_T("InHdr"))

`Parameters` (expressions not allowed) `:`

name- Header Name

`Returns:` sip_header_t

`*TYPECAST_SIP_HOSTNAME_T`

Convert text_t to sip_hostname_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_hostname_t : This object provides operations for parsing the SIP hostname as it appears at various places in the SIP protocol data. The format is abc.foo.com:5060.)

`Returns:` sip_hostname_t

`*TYPECAST_SIP_METHOD_T`

Convert text_t to sip_method_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_method_t : This object provides Text operations and SIP Request Method Enum operations on the SIP request method.)

`Returns:` sip_method_t

`*TYPECAST_SIP_TO_HEADER_T`

Convert text_t to sip_to_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_to_header_t : This object provides operations for parsing the SIP From header.)

`Returns:` sip_to_header_t

`*TYPECAST_SIP_URL_T`

Convert text_t to sip_url_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_url_t : SIP.REQ.URL provides operations for parsing and operating on the URL that is present in the first line of the SIP request header. The supported format is \[<protocol>://<hostname>\]<path>?<query>. The Text object backing a SIP URL object has the Text Mode set to URLENCODED by default.)

`Returns:` sip_url_t

`*TYPECAST_SIP_VERSION_T`

Convert text_t to sip_version_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_version_t : SIP.REQ.VERSION or SIP.RES.VERSION provide operations to extract SIP version information.)

`Returns:` sip_version_t

`*TYPECAST_SIP_VIA_HEADER_T`

Convert text_t to sip_via_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_via_header_t : This object provides operations for parsing the SIP Via header.)

`Returns:` sip_via_header_t

`*TYPECAST_SSLVPN_MODE_T`

Convert text_t to sslvpn_mode_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sslvpn_mode_t : This object provides Text operations and SSLVPN Mode Enum operations on the SSLVPN request method.)

`Returns:` sslvpn_mode_t

`*TYPECAST_SSL_TEXT_T` (text_t name)

Convert text_t to ssl_text_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ssl_text_t : Treat the underlying text object as SSL Text.)

`Parameters` (expressions not allowed) `:`

name- Name

`Returns:` ssl_text_t

`*TYPECAST_TCP_OPTIONS_T`

Convert text_t to tcp_options_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (tcp_options_t : TCP Protocol Options)

`Returns:` tcp_options_t

`*TYPECAST_TCP_OPTIONS_TYPE_T`

Convert text_t to tcp_options_type_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (tcp_options_type_t : TCP Protocol Options Type)

`Returns:` tcp_options_type_t

`*TYPECAST_TCP_REPEATER_OPTION_T`

Convert text_t to tcp_repeater_option_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (tcp_repeater_option_t : TCP Protocol Option : Repeater)

`Returns:` tcp_repeater_option_t

`*TYPECAST_TIME_AT`

Convert text_t to time_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (time_at : Treats a number value as number of seconds since GMT Jan 1 1970 0h 0m 0s.)

`Returns:` time_at

`*TYPECAST_TIME_LOCAL_AT`

Convert text_t to time_local_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (time_local_at : Treats a number value as number of seconds since GMT Jan 1 1970 0h 0m 0s as adjsuted for the local time zone.)

`Returns:` time_local_at

`*TYPECAST_TIME_T`

Convert text_t to time_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (time_t : This object treats a Text object as a date string. The formats supported are

1\. RFC822 :: Sun, 06 Nov 1994 08:49:37 GMT 2\. RFC850 :: Sunday, 06-Nov-94 08:49:37 GMT 3\. ASCTIME :: Sun Nov 6 08:49:37 1994 4\. ASCTIME like :: Sun Nov 6 08:49:37 1994 5\. ASCTIME like :: Sun Nov 06 08:49:37 1994 6\. Http Set-Cookie Expiry date :: Sun, 06-Nov-1994 08:49:37 GMT)

`Returns:` time_t

`*TYPECAST_UNSIGNED_LONG_AT`

Convert text_t to unsigned_long_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_at : Unsigned Long(64bit) Value)

`Returns:` unsigned_long_at

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error.)

`Parameters` (expressions not allowed) `:`

format- Format

`Returns:` unsigned_long_t

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format, ip_address_at default_value)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining

characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` unsigned_long_t

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format, unsigned_long_at default_value)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` unsigned_long_t

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format, num_at default_value)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` unsigned_long_t

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format, time_local_at default_value)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` unsigned_long_t

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format, time_at default_value)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` unsigned_long_t

`*TYPECAST_UNUM_TEXT_T`

Convert text_t to unum_text_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unum_text_t : Provides operations to treat the underlying OctectString as Binary String or unsigned long value .)

`Returns:` unum_text_t

`*TYPECAST_URL_CATEGORY_T`

Convert text_t to url_category_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (url_category_t : Retrieves URL category and attributes from an URL)

`Returns:` url_category_t

`*TYPECAST_VENDOR_SPEC_APPID_AVP_T`

Convert text_t to vendor_spec_appid_avp_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (vendor_spec_appid_avp_t : Retrieves AVPs that are nested in the grouped AVP Vendor-Specific-Application-Id (code 260). The nested AVPs are:

- Vendor-Id
- Auth-Application-Id
- Acct-Application-Id

For example, to retrieve the Auth-Application-Id AVP from the Vendor-Specific-Application-Id AVP:

- For requests:
  DIAMETER.REQ.VENDOR_SPECIFIC_APPLICATION_ID.AUTH_APPLICATION_ID
- For responses:
  DIAMETER.RES.VENDOR_SPECIFIC_APPLICATION_ID.AUTH_APPLICATION_ID

)

`Returns:` vendor_spec_appid_avp_t

`*TYPECAST_VENDOR_SPEC_RADIUS_AVP_T`

Convert text_t to vendor_spec_radius_avp_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (vendor_spec_radius_avp_t :

- Vendor-Id

To retrieve the Vendor-Id from the Vendor-Specific AVP:

- RADIUS.REQ.VENDOR_SPECIFIC.VENDORID

)

`Returns:` vendor_spec_radius_avp_t

`*UNQUOTE` (`char` c)

If selected text is quoted by character c, Remove character c from beginning and end.

For example: Say the selected text is / "foo xyz bar " /. Then on executing UNQUOTE("") the selected text will become /foo xyz bar / This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

c- Character

`Returns:` text_t

`*URLSET_MATCHES_ANY` (text_t urlset_name)

Results in Boolean TRUE value if and only if the Text matches any of the patterns that are specified in the urlset named by the string argument. The matching is case-insensitive for domains, but case-sensitive for paths. For example:

- HTTP.REQ.HOST.APPEND(HTTP.REQ.URL).URLSET_MATCHES_ANY("urlset_forbidden") returns true when the combined domain and URL matches any pattern in the urlset whose name is "urlset_forbidden".

`Parameters` (expressions not allowed) `:`

urlset_name- urlset name

`Returns:` bool_at

`*URL_CATEGORIZE` (`uint` min_reputation, `uint` max_reputation)

Returns the URL category for the supplied URL with the given minimum and maximum reputation score. Where a score of 5 is most risky and 1 is least risky. If either score is set to 0, that bound would be ignored. By specifying the reputation scores, the function will returned the category with the highest score (most risky) based on the bounds. If there was an error getting the category or if the URL is invalid then it will result in an Undef error. For example: HTTP.REQ.HOST.APPEND(HTTP.REQ.URL).URL_CATEGORIZE(0, 0) returns value when the combined domain and URL is looked up for the URL category with the highest reputation score (most risky).

`Parameters` (expressions not allowed) `:`

min_reputation- Minimum reputation score of URL category

max_reputation- Maximum reputation score of URL category

`Returns:` url_category_t

`*URL_RESERVED_CHARS_SAFE`

Converts URL reserved characters to corresponding '%XX' values and retains the rest. This is a read only operation.

```
Based on RFC3986, following are considered URL unreserved characters:

    Alpha-numeric characters: a-z, A-Z, 0-9

    Hyphen and underscore: "-", "_"

    Dot: "."

    Tilde: "~"
```

The rest are converted to %XX encoding, 'XX' is the hex-based representation of the input character. If the requirement is to encode all but URL safe characters, please consider using HTTP_URL_SAFE method.

`Returns:` text_t

`*XML_DECRYPT` (text_t certKeyName)

Decrypt the selected content, which was encrypted using the W3C XML Encryption standard.

`Parameters` (expressions not allowed) `:`

certKeyName- identifies the certkey object containing the RSA private key to be used to decrypt the bulk encryption key in the selected EncryptedData element.

`Returns:` text_t

`*XML_ENCRYPT` (text_t certKeyName, encrypt_method_e method)

Encrypt the selected cleartext using the W3C XML Encryption standard.

`Parameters` (expressions not allowed) `:`

certKeyName- identifies the certkey object containing an X.509 certificate with the RSA public key to be used to encrypt the generated bulk encryption key. Note that the certKey object need not, and usually will not, include the associated RSA private key.

method- specifies the bulk encryption method (rc4, des3, aes128, aes192, or aes256) used to encrypt the content.

`Returns:` text_t

`*XML_ENCRYPT` (text_t certKeyName, encrypt_method_e method, `uint` flags)

Encrypt the selected cleartext using the W3C XML Encryption standard.

`Parameters` (expressions not allowed) `:`

certKeyName- identifies the certkey object containing an X.509 certificate with the RSA public key to be used to encrypt the generated bulk encryption key. Note that the certKey object need not, and usually will not, include the associated RSA private key.

method- specifies the bulk encryption method (rc4, des3, aes128, aes192, or aes256) used to encrypt the content.

flags- optional bit mask to specify optional elements in the EncryptedData element. These are hints to tell the receiver what private key to use to decrypt the bulk encryption key, providing information from the certKey's X.509 certificate.

- 1 - include a KeyName element with the certKeyName;
- 2 - include a KeyValue element with the RSA public key from the certificate;
- 4 - include an X509IssuerSerial element with the certificate serial number and issuer DN;
- 8 - include an X509SubjectName element with the certificate subject DN;
- 16 - include an X509Certificate element with the entire certificate;

`Returns:` text_t

`*XPATH_HTML_WITH_MARKUP` (`xpath_str` xpathex)

Applies an XPath expression to the DOM for an HTML document and returns the selected node-set or string, including markup like element tags. node-sets are converted to strings using the standard XPath string conversion routine. The selected portion of the document can be used as the target for rewrite actions.

Examples: HTTP.REQ.BODY(1000).XPATH_HTML_WITH_MARKUP(xp%//md/head/title%) returns the <title> element in the document's <head> This can be used in a rewrite action to replace or delete the <title> element.

`Parameters` (expressions not allowed) `:`

xpathex- XPath Expression

`Returns:` text_t

`*XPATH_HTML` (`xpath_bool` xpathex)

Applies an XPath expression to the DOM for an HTML document and a boolean value.

Examples: HTTP.RES.BODY(1000).XPATH_HTML(xp%boolean(/md/head/meta)%) returns true if the <meta> element exists as a child of <head> element.

`Parameters` (expressions not allowed) `:`

xpathex- XPath Expression

`Returns:` bool_at

`*XPATH_HTML` (`xpath_double` xpathex)

Applies an XPath expression to the DOM for an HTML document and a double value.

Examples: HTTP.RES.BODY(1000).XPATH_HTML(xp%number(//video/@height)%) returns the numeric value of the height attribute of the first <video> element.

`Parameters` (expressions not allowed) `:`

xpathex- XPath Expression

`Returns:` double_at

`*XPATH_HTML` (`xpath_str` xpathex)

Applies an XPath expression to the DOM for an HTML document and returns the selected node-set or string. node-sets are converted to strings using the standard XPath string conversion routine.

Examples: HTTP.REQ.BODY(1000).XPATH_HTML(xp%//img/@src%) returns the string value of the src attribute of the first

```

HTTP_VERSION_T

HTTP.REQ.VERSION or HTTP.RES.VERSION provide operations to extract HTTP version information.

This topic lists the expressions that are provided by this class.

`*Note` *: Expressions with the * symbol are inherited / promoted from text_t

- `MAJOR`

  Operate as Number on the major component of the HTTP Version string.

`Returns:` num_t

`*MINOR`

Operate as Number on the minor component of the HTTP Version string.

`Returns:` num_t

`*TYPECAST_TEXT_T`

Convert http_version_t to text_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (text_t : Designates any piece of text.)

`Returns:` text_t

`*AFTER_REGEX` (`re` regex)

Selects the text after the portion that matches the given regular expression argument. The first match is returned when multiple matches occur in the text. The match may occur anywhere within the text - if you wish to "anchor" this, use "\^" at the start of the regex and/or "$" at the end of the regex. When the regular expression does not match the given string, a Text object of length of 0 is returned.

Example: HTTP.REQ.HEADER("etag").AFTER_REGEX(re/KX/) will select "DAPPER" from "KXDAPPER". This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

regex- Regular Expression

`Returns:` text_t

`*AFTER_STR_ANY` (text_t patset_name)

Selects the Text that is present after the first occurrence of any of the strings that are bound to the patset named by the string argument. If there is no match to any of the strings bound to the patset in the current Text object then the result Text object has 0 length. The patset cannot have strings longer than 255 characters. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` text_t

`*AFTER_STR` (text_t s)

Selects the Text that is present after the first occurrence of the string argument. If there is no match for the argument in the current Text then the result Text object has 0 length. The input string cannot be bigger than 255 characters. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*APPEND` (bool_at b)

Appends the given boolean's string representation to the current string.

`Parameters``:`

b- the boolean value to append.

`Returns:` text_t

`*APPEND` (double_at i)

Appends the given double's string representation to the current string.

`Parameters``:`

i- the double value to append.

`Returns:` text_t

`*APPEND` (ip_address_at addr)

Appends the given IPv4's string representation to the current string.

`Parameters``:`

addr- the IPv4 address to append.

`Returns:` text_t

`*APPEND` (num_at i)

Appends the given number's string representation to the current string.

`Parameters``:`

i- the number value to append.

`Returns:` text_t

`*APPEND` (time_local_at t)

Appends the given time's string representation to the current string.

`Parameters``:`

t- the time value to append.

`Returns:` text_t

`*APPEND` (time_at t)

Appends the given time's string representation to the current string.

`Parameters``:`

t- the time value to append.

`Returns:` text_t

`*APPEND` (unsigned_long_at i)

Appends the given unsigned long's string representation to the current string.

`Parameters``:`

i- the unsigned long value to append.

`Returns:` text_t

`*APPEND` (ipv6_address_at addr)

Appends the given IPv6's string representation to the current string.

`Parameters``:`

addr- the IPv6 address to append.

`Returns:` text_t

`*APPEND` (ipv6_subnet_at addr)

Appends the given IPv6 subnet's string representation to the current string.

`Parameters``:`

addr- the IPv6 subnet to append.

`Returns:` text_t

`*APPEND` (mac_address_at addr)

Appends the given MAC's string representation to the current string.

`Parameters``:`

addr- the MAC address to append.

`Returns:` text_t

`*APPEND` (text_t str)

Appends the given string to the current string.

`Parameters``:`

str- the string to append.

`Returns:` text_t

`*APPEND` (time_at t)

Appends the given time's string representation to the current string.

`Parameters``:`

t- the time value to append.

`Returns:` text_t

`*B64DECODE`

Decodes the selected text using base64 decoding.

For example, the string "TWFu" is converted to "Man"

`Returns:` text_t

`*B64ENCODE`

Encodes the selected text using base64 encoding.

For example, the string "Man" is converted to "TWFu"

`Returns:` text_t

`*BEFORE_REGEX` (`re` regex)

Selects the text before the portion that matches the given regular expression argument. The first match is returned when multiple matches occur in the text. The match may occur anywhere within the text - if you wish to "anchor" this, use "\^" at the start of the regex and/or "$" at the end of the regex. When the regular expression does not match the given string, a Text object of length of 0 is returned.

For example: HTTP.RES.HEADER("content-type").BEFORE_REGEX(re#/#) will select "text" from "text/plain". This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

regex- Regular Expression

`Returns:` text_t

`*BEFORE_STR_ANY` (text_t patset_name)

Selects the Text that is present before the first occurrence of any of the strings that are bound to the patset or datasetnamed by the string argument. If there is no match to any of the strings bound to the patset in the current Text object then the result Text object has 0 length. The patset cannot have strings longer than 255 characters. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` text_t

`*BEFORE_STR` (text_t s)

Selects the Text that is present before the first occurrence of the string argument. If there is no match for the argument in the current Text object then the result Text object has 0 length. The input string cannot be bigger than 255 characters. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*BETWEEN` (text_t start, text_t end)

Results in Boolean TRUE value if length of the Text object is greater than or equal to the sum of the Start and End argument lengths and if the prefix of the Text object matches the Start string argument and if the Suffix of the Text object matches the End string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

start- Start

end- End

`Returns:` bool_at

`*BIN_DECODE` (binary_encoding_e encoding)

Decode the encoded input into its original byte sequence. An incorrectly enooded input will result in an Undef error.

`Parameters` (expressions not allowed) `:`

encoding- specifies how the bytes are encoded.

`Returns:` text_t

`*BIN_ENCODE` (binary_encoding_e encoding)

Encode the input byte sequence. Note that BIN_ENCODE(hex_colons) is equivalent to BLOB_TO_HEX().

`Parameters` (expressions not allowed) `:`

encoding- specifies how the bytes are to be encoded.

`Returns:` text_t

`*BLOB_TO_HEX`

Convert to hexadecimal representation and select text.

For example, the byte string abc is converted to 61:62:63.

`Returns:` text_t

`*COMPARE` (text_t s)

Results in a Number Value which is the result of comparison of the input argument with the Text object. The result is greater than 0 if the Text object is lexicographically greater than the argument. The result is 0 if the Text object and the argument match. The result is less than 0 if the Text object is lexicographically lesser than the argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` num_at

`*CONTAINS_ANY` (text_t patset_name)

Results in Boolean TRUE value if the Text contains any of the strings that are bound to the patset or dataset named by the string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` bool_at

`*CONTAINS_INDEX` (text_t patset_name)

Returns the numerical index of the matching string, if the Text contains any of the strings that are bound to the patset or dataset named by the string argument. Returns 0 if there is no match. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` num_at

`*CONTAINS` (text_t s)

Results in Boolean TRUE value if the Text contains the string given in the argument. The input string cannot be bigger than 255 characters. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*CRC32`

Returns a 32-bit integer computed by applying a CRC (cyclic redundancy check) function to the selected text. This is the CRC function used by Ethernet, MPEG-2, PKZIP, GZIP, PNG, and many other applications. For example, the expression to compute the CRC value of the (first 1000 bytes of the) body of an HTTP request is: HTTP.REQ.BODY(1000).CRC32

`Returns:` num_at

`*DECODE_USING_TEXT_MODE`

Decodes the selected text using the currently configured text encoding methods like URLENCODED, BACKSLASH_ENCODED, PLUS_AS_SPACE, NOURLENCODED,

NO_BACKSLASH_ENCODED and NO_PLUS_AS_SPACE. Text encoding methods are set using SET_TEXT_MODE method.

`Returns:` text_t

`*DECRYPT`

Decrypt the selected base64-encoded ciphertext using the configured encryptionParams.

`Returns:` text_t

`*DECRYPT` (binary_encoding_e in_encoding)

Decrypt the selected ciphertext using the configured encryptionParams.

`Parameters` (expressions not allowed) `:`

in_encoding- specifies how the input ciphertext is encoded. If the ciphertext is not encoded as specified, causes an Undef error.

`Returns:` text_t

`*DECRYPT` (text_t encryptionKey)

Decrypt the selected base64-encoded encrypted bytes using the configured encryption key.

`Parameters` (expressions not allowed) `:`

encryptionKey- identifies the encryptionKey object to provide the cipher method, mode, padding, key, encrypted format and optional initialization vector (IV).

`Returns:` text_t

`*DECRYPT` (text_t encryptionKey, binary_encoding_e in_encoding)

Decrypt the selected base64-encoded encrypted bytes using the configured encryption key.

`Parameters` (expressions not allowed) `:`

encryptionKey- identifies the encryptionKey object to provide the cipher method, mode, padding, key, encrypted format, and optional initialization vector (IV).

in_encoding- specifies how the input ciphertext is encoded. If the ciphertext is not encoded as specified, causes an Undef error.

`Returns:` text_t

`*DIGEST` (digest_method_e method)

Returns a byte sequence computed by applying the the specified message digest method to the selected text.

`Parameters` (expressions not allowed) `:`

method- digest method to apply to the input text

`Returns:` text_t

`*ENCRYPT`

Encrypt the selected plaintext bytes using the configured encryptionParams. The resulting ciphertext is base64-encoded.

`Returns:` text_t

`*ENCRYPT` (binary_encoding_e out_encoding)

Encrypt the selected plaintext bytes using the configured encryptionParams.

`Parameters` (expressions not allowed) `:`

out_encoding- specifies how the resulting ciphertext is encoded.

`Returns:` text_t

`*ENCRYPT` (text_t encryptionKey)

Encrypt the selected cleartext bytes using the configured encryption key.

`Parameters` (expressions not allowed) `:`

encryptionKey- identifies the encryptionKey object to provide the cipher method, mode, padding, key, encrypted format and optional initialization vector (IV).

`Returns:` text_t

`*ENCRYPT` (text_t encryptionKey, binary_encoding_e out_encoding)

Encrypt the selected cleartext bytes using the configured encryption key.

`Parameters` (expressions not allowed) `:`

encryptionKey- identifies the encryptionKey object to provide the cipher method, mode, padding, key, encrypted format and optional initialization vector (IV).

out_encoding- specifies how the resulting ciphertext is encoded.

`Returns:` text_t

`*ENDSWITH_ANY` (text_t patset_name)

Results in Boolean TRUE value if the Text ends with any of the strings that are bound to the patset or dataset named by the string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` bool_at

`*ENDSWITH_INDEX` (text_t patset_name)

Returns the numerical index of the matching string, if the Text ends with any of the strings that are bound to the patset or dataset named by the string argument. Returns 0 if there is no match. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` num_at

`*ENDSWITH` (text_t end)

Results in Boolean TRUE value if a suffix of the Text object matches the string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

end- String

`Returns:` bool_at

`*EQUALS_ANY` (text_t patset_name)

Results in Boolean TRUE value if the Text equals any of the strings that are bound to the patset or dataset named by the string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` bool_at

`*EQUALS_INDEX` (text_t patset_name)

Returns the numerical index of the matching string, if the Text equals any of the strings that are bound to the patset or dataset named by the string argument. Returns 0 if there is no match. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` num_at

`*EQ` (text_t s)

Results in Boolean TRUE value if the Text object matches the input argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*GET_SIGNED16` (`uint` n, endian_e endianness)

Get the 16-bit signed binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

endianness- Select little or big endian

`Returns:` num_at

`*GET_SIGNED32` (`uint` n, endian_e endianness)

Get the 32-bit signed binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

endianness- Select little or big endian

`Returns:` num_at

`*GET_SIGNED8` (`uint` n)

Get the 8-bit signed binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

`Returns:` num_at

`*GET_UNSIGNED16` (`uint` n, endian_e endianness)

Get the 16-bit unsigned binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

endianness- Select little or big endian

`Returns:` num_at

`*GET_UNSIGNED32` (`uint` n, endian_e endianness)

Get the 32-bit unsigned binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

endianness- Select little or big endian

`Returns:` unsigned_long_at

`*GET_UNSIGNED64` (`uint` n, endian_e endianness)

Get the 64-bit unsigned binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

endianness- Select little or big endian

`Returns:` unsigned_long_at

`*GET_UNSIGNED8` (`uint` n)

Get the 8-bit unsigned binary integer at the given offset.

`Parameters``:`

n- Offset in bytes

`Returns:` num_at

`*GET_URLSET_METADATA` (text_t urlset_name)

Returns metadata value corresponding to pattern in the urlset. The matching is case-insensitive for domains, but case-sensitive for paths. If no pattern is matched within the urlset, the return value is a NULL string. For example:

- HTTP.REQ.HOST.APPEND(HTTP.REQ.URL).GET_URLSET_METADATA("urlset_forbidden") returns value when the combined domain and URL is looked up in the urlset whose name is "urlset_forbidden".

`Parameters` (expressions not allowed) `:`

urlset_name- urlset name

`Returns:` text_t

`*GE` (text_t s)

Results in Boolean TRUE value if the Text object is greater than or equal to the input argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*GRPC`

Interprets a text_t string as a Protocol Buffer (protocol_buffer_t type). Example: HTTP.REQ.BODY(1000).GRPC.STRING(1).EQ("bookname")

`Returns:` protocol_buffer_t

`*GT` (text_t s)

Results in Boolean TRUE value if the Text object is greater than the input argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*HASH`

Returns a positive 31 bit integer value computed by applying a proprietary NetScaler hash function to the selected text. This function is not case- sensitive and ignores whitespaces. For example, applying the HASH function to two strings "Ab c" and "abc" would produce the same value. This function should not be used for security purposes; use instead the DIGEST function with one of the standard digest methods.

`Returns:` num_at

`*HMAC` (text_t hmacKey)

Returns a byte sequence computed by applying the HMAC (Hash Message Authenticastion Code) function to the selected text using the configured HMAC key.

`Parameters` (expressions not allowed) `:`

hmacKey- indentifies the hmacKey object to provide the digest (hash) method and the key.

`Returns:` text_t

`*HMAC` (text_t hmacKey, binary_encoding_e out_encoding)

Returns a byte sequence computed by applying the HMAC (Hash Message Authenticastion Code) function to the selected text using the configured HMAC key .

`Parameters` (expressions not allowed) `:`

hmacKey- indentifies the hmacKey object to provide the digest (hash) method and the key.

out_encoding- specifies how the resulting HMAC is encoded.

`Returns:` text_t

`*HTML_XML_SAFE`

Apply XML safe transform and select text.

Converts '<', '>' and '&' in the input text to '<', '>' and '&' respectively; other characters in the input are not modified. This transform safeguards against XSS based attacks. This is a read only operation.

`Returns:` text_t

`*HTTP_HEADER_SAFE`

Apply Header safe transform and select text. Converts all new line ('\\n') characters present in the input text to '%0A' so that they can safely be used in HTTP headers. This transform safeguards against response-splitting attacks. This is a read only operation.

`Returns:` text_t

`*HTTP_URL_SAFE`

Apply URL safe transform and select text. Converts URL unsafe characters to corresponding '%xx' values and retains the rest. This is a read only operation.

```
Based on RFC2396, following are considered URL safe characters:

    Alpha-numeric characters: a-z, A-Z, 0-9

    Hyphen and underscore: "-", "_"

    Dot: "."

    Exclamation mark: "!"

    Tilde: "~"

    Asterix: "&ast;"

    Single quote: "'"

    Open and close parentheses: "(", ")"
```

```
    Semi-colon: ";"

    Colon: ":"

    At symbol: "@"

    Question mark: "?"

    Equals: "="

    Dollar: "$"

    Percent: "%"

    Ampersand: "&"

    Plus: "+"

    Comma: ","

    Forward slash: ".html"
```

The rest are converted to %XX encoding, 'XX' is the hex-based representation of the input character. If the requirement is to encode all but URL unreserved characters, please consider using URL_RESERVED_CHARS_SAFE method.

`Returns:` text_t

`*IS_BOOL_AT`

Results in Boolean TRUE value if the Text is of boolean type.

`Returns:` bool_at

`*IS_DOUBLE_AT`

Results in Boolean TRUE value if the Text is of double data type.

`Returns:` bool_at

`*IS_IPV6_AT`

Results in Boolean TRUE value if the Text is of IPv6 data type.

`Returns:` bool_at

`*IS_IPV6_SUBNET_AT`

Results in Boolean TRUE value if the Text is of IPv6 subnet data type.

`Returns:` bool_at

`*IS_IP_AT`

Results in Boolean TRUE value if the Text is of IPv4 data type.

`Returns:` bool_at

`*IS_MAC_ADDRESS_AT`

Results in Boolean TRUE value if the Text is of mac address data type.

`Returns:` bool_at

`*IS_NUM_AT`

Results in Boolean TRUE value if the Text is of number type.

`Returns:` bool_at

`*IS_NUM_AT` (num_format_e format)

Results in Boolean TRUE value if the Text is of number type with given input base.

`Parameters` (expressions not allowed) `:`

format- number format

`Returns:` bool_at

`*IS_STRINGMAP_KEY` (text_t string_map_name)

Returns true if the string that it operates on is present in the string map. Text mode IGNORECASE, NOIGNORECASE - controls whether key lookup in string map is case sensitive or not. For example:

- HTTP.REQ.URL.IS_STRINGMAP_KEY("url_stringmap") returns true if value of HTTP.REQ.URL is present as key in the string map whose name is "url_stringmap".

- HTTP.REQ.URL.SET_TEXT_MODE(IGNORECASE). IS_STRINGMAP_KEY("url_stringmap") returns true if value of HTTP.REQ.URL is present as key in the string map whose name is "url_stringmap". Key lookup in this case is done case-insensitively.

`Parameters` (expressions not allowed) `:`

string_map_name- identifies the string map.

`Returns:` bool_at

`*IS_TIME_AT`

Results in Boolean TRUE if the Text follows any of the standard time formats given below, otherwise false. Tue, 05 Nov 1994 08:12:31 GMT RFC822 Tuesday, 05-Nov-94 08:12:31 GMT RFC850 Tue Nov 4 08:12:31 1994 asctime

`Returns:` bool_at

`*IS_UNSIGNED_LONG_AT`

Results in Boolean TRUE value if the Text is of unsigned long data type.

`Returns:` bool_at

`*IS_UNSIGNED_LONG_AT` (num_format_e format)

Results in Boolean TRUE value if the Text is of unsigned long data type with given input base.

`Parameters` (expressions not allowed) `:`

format- number format

`Returns:` bool_at

`*JWT_VERIFY_CERTKEY` (text_t certkey_name)

Verifies the signature on the input JSON Web Token (JWT), using the RSA public key in the X.509 certificate in the specified certkey object. The token has the format HEADER.PAYLOAD.SIGNATURE where

- HEADER is a base64-encoded JSON structure indicating a signature algorithm and token type, e.g.'{"alg":"RS256","typ":"JWT"}'
- PAYLOAD is a base64-encoded JSON structure with asserted claims, e.g. '{"loggedInAs":"admin","iat":1422779638}'

- SIGNATURE is the base64-encoded bytes for the signature on HEADER.PAYLOAD.

Returns true if the signature is verified for the header and payload using the specified public key; false if the signature is not verified

`Parameters``:`

certkey_name- identifies the certkey object containing an X.509 certificate holding the RSA public key. Results in an Undef error if the certkey object does not exist or does not contain an X.509 certificate with an RSA public key, if the token is not correctly formatted, or if the verification operation cannot complete.

`Returns:` bool_at

`*JWT_VERIFY_XML` (text_t xml_pkey)

Verifies the signature on the input JSON Web Token (JWT), using the RSA public key supplied by the specified XML element. The token has the format HEADER.PAYLOAD.SIGNATURE where

- HEADER is a base64-encoded JSON structure indicating a signature algorithm and token type, e.g.'{"alg":"RS256","typ":"JWT"}'
- PAYLOAD is a base64-encoded JSON structure with asserted claims, e.g. '{"loggedInAs":"admin","iat":1422779638}'
- SIGNATURE is the base64-encoded bytes for the signature on HEADER.PAYLOAD.

Returns true if the signature is verified for the header and payload using the specified public key; false if the signature is not verified

`Parameters``:`

xml_pkey- an expression that supplies an <RSAKeyValue> element with the public key. Results in an Undef error if the XML element is invalid or does not correctly specify an RSA public key, if the token is not correctly formatted, or if the verification operation cannot complete.

`Returns:` bool_at

`*LENGTH`

Results in a Number Value that is the number of characters (not bytes) in the Text object.

`Returns:` num_at

`*LE` (text_t s)

Results in Boolean TRUE value if the Text object is less than or equal to the input argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*LOCATION_LONG`

Get the location qualifier from CLIENT.IP.SRC.LOCATION.GET(n) (ISO short name) and then convert it to human readable long name. This conversion is valid only for country names. Correct Country qualifier value (number) in GET(n) is left up to the user as qualifiers are user configurable. Expression example: CLIENT.IP.SRC.LOCATION.GET(1).LOCATION_LONG For example: Data from each expression CLIENT.IP.SRC.LOCATION: NA.US.California.SantaClara.*.* CLIENT.IP.SRC.LOCATION.GET(1): US CLIENT.IP.SRC.LOCATION.GET(1).LOCATION_LONG: United States

`Returns:` text_t

`*LT` (text_t s)

Results in Boolean TRUE value if the Text object is less than the input argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*MAP_STRING_DEFAULT_TO_KEY` (text_t string_map_name)

Returns the value corresponding to the key in the string map. This is similar to the MAP_STRING method, but if the key is not present then instead of returning a null string, it returns the key itself. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed)`:`

string_map_name- identifies the string map.

`Returns:` text_t

`*MAP_STRING` (text_t string_map_name)

Returns value corresponding to key in the string map. Key is the string that it is given as input. Text mode IGNORECASE, NOIGNORECASE - controls whether key lookup in string map is case sensitive or not. For example:

- HTTP.REQ.URL.MAP_STRING("url_stringmap") returns value when the value of HTTP.REQ.URL is used as key in the string map whose name is "url_stringmap".
- HTTP.REQ.URL.SET_TEXT_MODE(IGNORECASE). MAP_STRING("url_stringmap") returns value when the value of HTTP.REQ.URL is used as key in the string map whose name is "url_stringmap". Key lookup in this case is done case-insensitively.

`Parameters` (expressions not allowed) `:`

string_map_name- identifies the string map.

`Returns:` text_t

`*MARK_SAFE`

Mark the PIXL expression safe without applying any safe transform.

`Returns:` text_t

`*MAX` (text_t s)

Compares the string argument with the current string and returns the max string. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*MIN` (text_t s)

Compares the string argument with the current string and returns the min string. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*NE` (text_t s)

Results in Boolean TRUE value if the Text object is not equal to the input argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` bool_at

`*NORMALIZE_URL`

Normalize URL. Normalizes a URL by doing "percent" decoding. See the description for URLENCODED in the SET_TEXT_MODE function. This performs the equivalent of SET_TEXT_MODE(URLENCODED).DECODE_USING_TEXT_MODE, except that it does not change the value of the current text mode.

`Returns:` text_t

`*PKEY_ENCRYPT_PEM_NO_PADDING` (text_t pem_pkey)

Encrypts the input text using the RSA public key provided by the PEM string and RSA_NO_PADDING padding method. The input text to be encrypted cannot be longer than the public key length minus 11 bytes for padding. For example, for a 1024-bit (128 byte) key, the input text cannot be longer than 128 - 11 = 117 bytes. An Undef error will occur if the input text is too long. A null input will also cause an Undef error. Returns the (unencoded binary) encrypted text, which is typically base-64 encoded for use in a message.

`Parameters``:`

pem_pkey- a text expression that supplies a RSA public key in the PEM format. If the text value is not a valid PEM RSA PUBLIC KEY encoding, an Undef error will occur. Example (a 1024-bit public key):

```
"-----BEGIN RSA PUBLIC KEY-----" +

"MIGJAoGBAKl5vgQEj73Kxp+9yn1v5gPR1pnc4oLM2a0kaWwBOsB6rzCIy6znwnvw" +

"CY1xRvQhRlJSAyJbloL7wZFIJ2FOR8Cz+8ZQWXU2syG+udi4EnWqLgFYowF9zK+o" +

"79az597eNPAjsHZ/C2oL/+6qY5a/f1z8bQPrHC4GpFfAEJhh/+NnAgMBAAE=" +
```

```
"-----END RSA PUBLIC KEY-----"
```

`Returns:` text_t

`*PKEY_ENCRYPT_PEM` (text_t pem_pkey)

Encrypts the input text using the RSA public key provided by the PEM string and the RSA_PKCS1_PADDING padding method. The input text to be encrypted cannot be longer than the public key length minus 11 bytes for padding. For example, for a 1024-bit (128 byte) key, the input text cannot be longer than 128 - 11 = 117 bytes. An Undef error will occur if the input text is too long. A null input will also cause an Undef error. Returns the (unencoded binary) encrypted text, which is typically base-64 encoded for use in a message.

`Parameters``:`

pem_pkey- a text expression that supplies a RSA public key in the PEM format. If the text value is not a valid PEM RSA PUBLIC KEY encoding, an Undef error will occur. Example (a 1024-bit public key):

```
"-----BEGIN RSA PUBLIC KEY-----" +

"MIGJAoGBAKl5vgQEj73Kxp+9yn1v5gPR1pnc4oLM2a0kaWwBOsB6rzCIy6znwnvw" +

"CY1xRvQhRlJSAyJbloL7wZFIJ2FOR8Cz+8ZQWXU2syG+udi4EnWqLgFYowF9zK+o" +

"-----END RSA PUBLIC KEY-----"
```

`Returns:` text_t

`*PKEY_SIGN_CERTKEY` (text_t certkey_name)

Generates a binary digital signature using the SHA-256 message digest function and an RSA private key from the specified SSL certKey object.

`Parameters``:`

certkey_name- identifies the configured certKey object. Results in an Undef error if the certkey object does not exist or does not contain an RSA private key, or if the signing operation cannot complete.

`Returns:` text_t

`*PKEY_SIGN_XML` (text_t xml_pkey)

Generates a binary digital signature using the SHA-256 message digest function and an RSA private key from the specified XML element.

`Parameters``:`

xml_pkey- an expression that supplies an <RSAKeyValue> element with the private key. Example: <RSAKeyValue> <Modulus>qXm+BASPvcrGn73KfW/
mA9HWmdzigszZrSRpbAE6wHqvMIjLrOfCe/
AJjXFG9CFGUlIDIluWgvvBkUgnYU5HwLP7xlBZdTazIb652LgSdaouAVijAX3Mr6jv1rPn3t408COwdn8Lagv/
7qpjlr9/XPxtA+scLgakV8AQmGH/42c=</Modulus> <Exponent>AQAB</Exponent>"zNjysxcIJV/
J9cTpIgPp2/x1IXHT5GTH8OMuNad0qtRSLjU1QYUmmkm9QcJJAN+7h8FEXWGabySUzBrHj/
IEbw==" <DP>QavUDQLLQpnPJXtVAo6CYhxOMCd68mwTxYKKNLjmC0pd54SFHllTLPE1FZU5EjK6q3nCeijonpfH+XX
DP> <DQ>EiXOKouJzzXTQJC3TqomF7Uf81yQNxWumOqnd11kepXgyfMwyqMvLlAGEkNSEF/
Bz18R3Wv+MIZ/IC3nLBt2xQ==</DQ> <InverseQ>ocuCmz36CP+N2aGqxaU+BKD5+3RLgRq9LFhULEz2jKx0iV9r76jsAxn3sLcTYYO9eqRPy2cz74A
nw==</InverseQ> <D>fTBD773a3GzcmgVdfZlaBLpN1ux2mf5uUVrTUQf7eVFm9egm4/
tzC5A9zjC+I/oscwTH8epL3UfRLdtp05Q6pWfJBXEnGo0QmOFFBK4pLx/
5JJpPGZ69ovDFEVOUHyiCfKE/g97T4WX3us0nFe1272zwGlHarM1YYwvfeE08UdE=</D> </
RSAKeyValue> Results in an Undef error if the XML element is invalid or does not correctly specify an RSA private key, or if the signing operation cannot complete.

`Returns:` text_t

`*PKEY_VERIFY_CERTKEY` (text_t certkey_name, text_t signature)

Verifies if the input text matches the specified signature generated using the SHA-256 messge digest function and the RSA private key associated with the specified RSA public key in the X.509 certificate in the specified certKey object. Returns true if the signature is verified, false otherwise.

`Parameters``:`

certkey_name- identifies the certkey object containing an X.509 certificate holding the RSA public key.

signature- the binary signature. Results in an Undef error if the certkey object does not exist or does not contain an X.509 certificate with an RSA public key, or if the verification operation cannot complete.

`Returns:` bool_at

`*PKEY_VERIFY_XML` (text_t xml_pkey, text_t signature)

Verifies if the input text matches the specified signature generated using the SHA-256 messge digest function and the RSA private key associated with the RSA public key supplied by the specified XML element. Returns true if the signature is verified, false otherwise.

`Parameters``:`

xml_pkey- an expression that supplies an <RSAKeyVAlue> element with the public key. Example: <RSAKeyValue> <Modulus>qXm+BASPvcrGn73KfW/mA9HWmdzigszZrSRpbAE6wHqvMIjLrOfCe/AJjXFG9CFGUlIDIluWgvvBkUgnYU5HwLP7xlBZdTazIb652LgSdaouAVijAX3Mr6jv1rPn3t408COwdn8Lagv/7qpjlr9/XPxtA+scLgakV8AQmGH/42c=</Modulus> <Exponent>AQAB</Exponent> </RSAKeyValue>

signature- the binary signature. Results in an Undef error if the XML element is invalid or does not correctly specify an RSA public key, or if the verification operation cannot complete.

`Returns:` bool_at

`*PREFIX` (`char` c, `uint` i)

Select a prefix of the Text. The selected prefix is the longest prefix that has at most Count (2nd argument) occurrences of character in the 1st argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

c- Character

i- Count

`Returns:` text_t

`*PREFIX` (`uint` i)

Select a prefix of the Text. The length of the prefix is equal to the number in the argument. If there aren't enough characters in the Text object then the entire Text is selected.

`Parameters``:`

i- Prefix Length

`Returns:` text_t

`*REGEX_MATCH` (`re` regex)

Returns TRUE if and only if the text contains at least one match of the regular expression argument. The match may occur anywhere within the text - if you wish to "anchor" this, use "\^" at the start of the regex and/or "$" at the end of the regex.

The regular expression has to be of the format: `re<delimiter>regular expression<same delimiter>`

The regular expression cannot be bigger than 1499 characters.

The regular expression should be acceptable by the PCRE regular expression library. Look at http://www.pcre.org/pcre.txt for documentation on the regular expression syntax. In particular, look at the pcrepattern man page.

There are some differences in the allowed syntax w.r.t PCRE syntax. Backreferences are not allowed. It is recommended not to use recursive regular expressions. The dot metacharacter matches newlines also. Unicode is not supported. SET_TEXT_MODE(IGNORECASE) overrides the (?i) internal option specified in the regular expression.

The PCRE library configuration can be seen in the system log, after executing 'nsapimgr -B" call ns_pixl_regex_show_config()"' at the shell prompt.

Some examples:

- HTTP.REQ.HOSTNAME.REGEX_MATCH(re/\[\[:alpha:\]\]+(abc){2,3}/)
- HTTP.REQ.URL.SET_TEXT_MODE(URLENCODED).REGEX_MATCH(re#(a*b+c*)#)
- HTTP.REQ.URL.REGEX_MATCH(re/a(?i)b/) matches ab and aB
- HTTP.REQ.URL.SET_TEXT_MODE(IGNORECASE).REGEX_MATCH(re/ab/) matches ab, aB, Ab and AB
- HTTP.REQ.BODY.REGEX_MATCH(re/(?ixm) (\^ab (.*) cd$) /) does a case-insensitive, multiline match where the dot metacharacter matches newline also. The regex itself can contain whitespace which will be ignored during the matching (x - extended regex).

This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

regex- Regular Expression

`Returns:` bool_at

`*REGEX_REPLACE` (`re` regex, text_t replacement, replacemode_e mode)

Selects the text that matches the given regular expression argument and replaces it with the the text given in the second argument. The third argument specifies whether the first match is only replaced when multiple matches occur in the text or all matches are replaced. The match may occur anywhere within the text - if you wish to "anchor" this, use "\^" at the start of the regex and/or "$" at the end of the regex. When the regular expression does not match the given string then the same string is returned.

For example: HTTP.RES.BODY(999).REGEX_REPLACE(re!\\bpassword:\\s*\\b!, "password: ***", ALL) will replace all occurrences of "password:" with "password: ***" This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

regex- Regular Expression

replacement- String to replace the match

mode- Mode of replacement

`Returns:` text_t

`*REGEX_SELECT` (`re` regex)

Selects the text that matches the given regular expression argument. The first match is returned when multiple matches occur in the text. The match may occur anywhere within the text - if you wish to "anchor" this, use "\^" at the start of the regex and/or "$" at the end of the regex. When the regular expression does not match the given string, a Text object of length of 0 is returned.

For example: HTTP.REQ.HEADER("via").REGEX_SELECT(re!NS-CACHE-\\d\\.\\d:\\s*\\d{1,3}!) will select "NS-CACHE-7.0: 70" This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

regex- Regular Expression

`Returns:` text_t

`*REPEAT` (`uint` i)

Produces a string which contains 'i' sequential copies of the input string.

`Parameters``:`

i- the number of times to repeat the string (0 or more)

`Returns:` text_t

`*SET_CHAR_SET` (charset_e charset)

Set the character set to use for subsequent functions that use text.

`Parameters` (expressions not allowed) `:`

charset- Character Set

`Returns:` http_version_t

`*SET_TEXT_MODE` (textmode_e mode)

The mode setting of a Text object controls the behavior of many Text operations. The Text mode settings may also control the behavior of some operations in objects (like List) that build upon the Text object. IGNORECASE, NOIGNORECASE - controls whether string comparison is case sensitive or not. URLENCODED - If set then all Text operations are carried out after translating all %HH or %uHHHH encodings in the underlying byte stream. 1. %HH will be translated to the character Y where HH denotes the ascii value of character Y in hexadecimal. For example, the encoded text "http%3a/.html" will be decoded to "http:/.html" 2. %uWWHH will be translated to the character sequence YZ where WW denotes the ascii value of character Y in hexadecimal and HH denotes the ascii value of character Z in hexadecimal. For example, the encoded text "http%u3a2f.html" and "http%u003a/.html" will both be decoded to"http:/.html" NOURLENCODED - Indicates that no percent encodings are present in the Text object. No percent decoding will be performed on the Text object. PLUS_AS_SPACE - If set then all Text operations are carried out after converting occurrences of the plus character to whitespace. For example, the text "hello+world" will be decoded to "hello world" NO_PLUS_AS_SPACE - If set, then the plus character will not be converted to whitespace in the Text object. BACKSLASH_ENCODED - If set, then all Text operations are carried out after performing the following operations: 1. \\XXX will be translated to the character Y where XXX denotes the ascii value of character Y in octal. The valid range of octal values for this type of encoding is \\0 to \\377. For example, the encoded text "http\

\72/.html" and "http\\072/.html" will both be decoded to "http:/.html" 2. \\xHH will be translated to the character Y where HH denotes the ascii value of character Y in hexadecimal. For example, the encoded text "http\\x3a/.html" will be decoded to "http:/.html" 3. \\\\uWWXX will be translated to the character sequence YZ where WW denotes the ascii value of character Y in hexadecimal and XX denotes the ascii value of character Z in hexadecimal. For example, the encoded text "http%u3a2f.html" and "http%u003a/.html" will both be decoded to"http:/.html" 4. Occurences of "\ \b", "\\n", "\\t", "\\f" and "\\r" are translated to the corresponding ascii characters. NO_BACKSLASH_ENCODED - If set, then backslash decoding will not be performed on the Text object. BAD_ENCODE_RAISE_UNDEF - If set, then UNDEF is raised if either the URLENCODED or BACKSLASH_ENCODED mode is set and a bad encoding corresponding to the specified encoding mode is encountered. NO_BAD_ENCODE_RAISE_UNDEF - If set, then UNDEF will not be raised when a bad encoding is encountered in the Text object. The Text operations operate on characters (as opposed to operating on bytes). By default a single byte represents a character using the ASCII encoding. But if URLENCODED mode is set then 3 bytes may represent a character. A PREFIX(3) operation will select the first 3 characters in the Text object. That means it may select up to 9 bytes for URLENCODED Text object. In the case of multibyte decodings as a result of %uXXXX or \\\\uXXXX, Text operations which attempt to treat the multiple decoded bytes as distinct characters are not allowed.

`Parameters` (expressions not allowed) `:`

mode- Text Mode

`Returns:` http_version_t

`*SKIP` (`char` c, `uint` i)

Select the Text after skipping over a prefix of the current Text. The skipped over prefix is the longest prefix that has at most Count (2nd argument) occurrences of character in the 1st argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

c- Character

i- Count

`Returns:` text_t

`*SKIP` (`uint` i)

Select the Text after skipping over a prefix in the current Text. The length of the prefix is equal to the number in the argument. If there aren't enough characters in the Text object then the entire Text is skipped over.

`Parameters` (expressions not allowed) `:`

i- Prefix Length

`Returns:` text_t

`*STARTSWITH_ANY` (text_t patset_name)

Results in Boolean TRUE value if the Text starts with any of the strings that are bound to the patset or dataset named by the string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` bool_at

`*STARTSWITH_INDEX` (text_t patset_name)

Returns the numerical index of the matching string, if the Text starts with any of the strings that are bound to the patset or dataset named by the string argument. Returns 0 if there is no match. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` num_at

`*STARTSWITH` (text_t start)

Results in Boolean TRUE value if a prefix of the Text object matches the string argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

start- String

`Returns:` bool_at

`*STRIP_CHARS` (text_t s)

From the selected text remove the characters specified in the string.

For example: Say the selected text is / "foo.xyz=bar" /. Then on executing STRIP_CHARS('.=') or STRIP_CHARS('..=') the selected text will become /fooxyzbar /. Note that repeating character has same effect as it would be if it present only once. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*STRIP_END_CHARS` (text_t s)

Selects the Text after stripping off characters in the end of the current Text object.

For example: Say the selected text is / "foo.xyz=bar" /. Then on executing STRIP_END_CHARS('ar') the selected text will become /foo.xyz=b /. Note that repeating character has same effect as it would be if it present only once. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*STRIP_END_WS`

Selects the Text after stripping off white space in the end of the current Text object.

`Returns:` text_t

`*STRIP_START_CHARS` (text_t s)

Selects the Text after stripping off characters in the beginning of the current Text object.

For example: Say the selected text is / "foo.xyz=bar" /. Then on executing STRIP_START_CHARS('of') the selected text will become /.xyz=bar /. Note that repeating character has same effect as it would be if it present only once. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*STRIP_START_WS`

Selects the Text after stripping off white space in the beginning of the current Text object.

`Returns:` text_t

`*SUBSTR_ANY` (text_t patset_name)

Select any one sub-string that matches any string in the given patset or dataset. The patset cannot have strings longer than 255 characters. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

patset_name- Pattern Set Name

`Returns:` text_t

`*SUBSTR` (`uint` start, `uint` len)

Select the Text object of the given length at the given offset. Offset it 0 based. If there aren't enough characters after the offset then all the remaining characters are selected.

`Parameters``:`

start- Offset

len- Length

`Returns:` text_t

`*SUBSTR` (text_t s)

Select the first Text object that matches the input string argument. The input string cannot be bigger than 255 characters. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

s- String

`Returns:` text_t

`*SUFFIX` (`char` c, `uint` i)

Select a suffix of the Text. The selected suffix is the longest possible suffix containing at most Count (2nd arg) occurrences of the character in the 1st argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

c- Character

i- Count

`Returns:` text_t

`*SUFFIX` (`uint` i)

Select a suffix of the Text. The length of the suffix is equal to the number in the argument. If there aren't enough characters in the Text object then the entire Text is selected.

`Parameters``:`

i- Suffix Length

`Returns:` text_t

`*TO_LOWER`

Converts the selected text to lower case.

For example, the string "ABCd" is converted to "abcd"

`Returns:` text_t

`*TO_UPPER`

Converts the selected text to upper case.

For example, the string "abcD" is converted to "ABCD"

`Returns:` text_t

`*TRUNCATE` (`char` c, `uint` i)

Select the Text after truncating a suffix from the current Text object. The truncated suffix is the longest possible suffix containing at most Count (2nd arg) occurrences of the character in the 1st argument. This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters``:`

c- Character

i- Count

`Returns:` text_t

`*TRUNCATE` (`uint` i)

Select the Text after truncating a suffix of the Text. The length of the suffix truncated is equal to the number in the argument. If there aren't enough characters in the Text then then all the characters are truncated.

`Parameters``:`

i- Suffix Length

`Returns:` text_t

`*TYPECAST_AVP_T`

Convert text_t to avp_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (avp_t : Operations that can be performed on the returned AVPs.

`Note:` An AVP can have multiple instances in a Diameter message. However, the system can access only the first 16 instances.

`Example:`

- To get the first value of AVP code 266 from a request, use: DIAMETER.REQ.AVP(266).VALUE(0).
- To get the fourth value of AVP code 266 from a request, use: DIAMETER.REQ.AVP(266).VALUE(3).
- To check if AVP code 1000 in the response has the vendor-specific bit set, use: DIAMETER.RES.AVP(1000).IS_VENDOR_SPECIFIC.

)

`Returns:` avp_t

`*TYPECAST_AVP_UNUM_T`

Convert text_t to avp_unum_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (avp_unum_t : In Diameter AVP based expressions can be written as DIAMETER.REQ.AVP(<avpcode>). For example Auth-Application-Id AVP (AVP code 258) can be extracted as DIAMETER.REQ.AVP(258) For few of the important AVPs we provide aliases. For example this AVP based expression can also be written as DIAMETER.REQ.AUTH_APPLICATION_ID. This expression returns either a object of class avp_t or returns a numerical value (object of class unsigned_long_at). The numerical value for this object is derived from the value in first instance of the AVP.)

`Returns:` avp_unum_t

`*TYPECAST_BOOL_AT`

Convert text_t to bool_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (bool_at : Boolean Operations)

`Returns:` bool_at

`*TYPECAST_COOKIE_T`

Convert text_t to cookie_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (cookie_t : The HTTP Cookie type provides operations for a cookie as it appears in the Set-Cookie and Set-Cookie2 header. In this type the Name-Value List operations are also available. The first delimiter is = and the element delimiter is ;. Multiple consecutive ; are treated as one. (Same as applying the method IGNORE_EMPTY_ELEMENTS on a Name-Value List.) You can use the Name-value List operations to access cookie attributes. The name comparison for all list operations is case insensitive. In this type Text operations are also available. Each cookie begins with a COOKIE_NAME=COOKIE_VALUE pair followed by zero or more semi-colon separated attribute-value pairs. If an attribute appears more than once in a cookie, the value associated with the first appearance of the attribute is returned.

Format Cookie: Cookie1=Value;Version=decimal;Value;Domain=Value;Path=Value)

`Returns:` cookie_t

`*TYPECAST_DIAMETER_FLAG_T`

Convert text_t to diameter_flag_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (diameter_flag_t : Provides operation to treat the underlying 1 byte as set of bit flags. then set/unset/test/reset_all operations can be done on flag)

`Returns:` diameter_flag_t

`*TYPECAST_DNS_DOMAINNAME_T`

Convert text_t to dns_domainname_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (dns_domainname_t : This object provides operations for parsing the DNS domain name as it appears at various places in the DNS data. The format is abc.foo.com.)

`Returns:` dns_domainname_t

`*TYPECAST_DNS_FLAG_T`

Convert text_t to dns_flag_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (dns_flag_t : Provides operations to test/set/unset a flag in dns header.)

`Returns:` dns_flag_t

`*TYPECAST_DOUBLE_AT`

Convert text_t to double_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_at : Double Value)

`Returns:` double_at

`*TYPECAST_DOUBLE_T` (double_format_e format)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error.)

`Parameters` (expressions not allowed) `:`

format- Format

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, double_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, ip_address_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, num_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one

or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, time_local_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, time_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_DOUBLE_T` (double_format_e format, unsigned_long_at default_value)

Convert text_t to double_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (double_t : Treat the underlying text as a Double in the given format. The supported formats are DECIMAL, DECIMAL_PREFIX. All the formats strip off the beginning white space. DECIMAL also strips off trailing white space. DECIMAL requires that all the remaining characters must be a proper double value. DECIMAL_PREFIX requires that at least one or more more characters in the prefix must be a proper double value. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Double

`Returns:` double_t

`*TYPECAST_HTTP_CACHE_CONTROL_T`

Convert text_t to http_cache_control_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_cache_control_t : This object provides for the ability to work on HTTP Cache-Control headers. The name comparison for all list operations is case insensitive.)

`Returns:` http_cache_control_t

`*TYPECAST_HTTP_CONTENT_LENGTH_T`

Convert text_t to http_content_length_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_content_length_t : The HTTP.REQ.CONTENT_LENGTH or HTTP.RES.CONTENT_LENGTH object can be treated as a HTTP Header or as a Number. The numerical value for this object is derived from the value in the last instance of the Content-Length header.)

`Returns:` http_content_length_t

`*TYPECAST_HTTP_COOKIE_T`

Convert text_t to http_cookie_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_cookie_t : This object provides operations for parsing

the HTTP cookie header. The name-value pair is derived from the value in the last instance of Cookie header. The format is Cookie : name0=value0; name1=value1; An HTTP Cookie header can have multiple occurrences. COUNT will return a Number containing how many headers of the current type exist. The name comparison for all list operations is case insensitive. The system does not keep track of more than 15 HTTP headers. The result will be undefined if there are more than 15 instances of the header.)

`Returns:` http_cookie_t

`*TYPECAST_HTTP_DATE_T`

Convert text_t to http_date_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_date_t : The HTTP.REQ.DATE or HTTP.RES.DATE object can be treated as a HTTP header or a Time object. The Time value is derived from the value in the last instance of the Date header. The date formats supported are RFC 822 (updated by RFC 1123), RFC 1036 (obsoletes RFC850) and ANSI C asctime() formats.)

`Returns:` http_date_t

`*TYPECAST_HTTP_HEADER_T` (text_t name)

Convert text_t to http_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_header_t : When typecasting a Text object to HTTP Header a header name must be provided.For example: HTTP.REQ.HEADER("MyHdr").TYPECAST_HTTP_HEADER_T("InHdr"))

`Parameters` (expressions not allowed) `:`

name- Header Name

`Returns:` http_header_t

`*TYPECAST_HTTP_HOSTNAME_T`

Convert text_t to http_hostname_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_hostname_t : This object provides operations for parsing the HTTP hostname as it appears at various places in the HTTP protocol data. The format is abc.foo.com:8080.)

`Returns:` http_hostname_t

`*TYPECAST_HTTP_METHOD_T`

Convert text_t to http_method_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_method_t : This object provides Text operations and HTTP Request Method Enum operations on the HTTP request method.)

`Returns:` http_method_t

`*TYPECAST_HTTP_SET_COOKIE_T`

Convert text_t to http_set_cookie_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_set_cookie_t : HTTP.RES.SET_COOKIE provides operations for parsing and operating on the SET-COOKIE header that is present in the HTTP response. HTTP Set-Cookie header supports Text and HTTP Header operations. For most Text operations the value in the last Set-Cookie header is selected. HTTP Set-Cookie header also supports special operations to extract cookies from the response. It is assumed that there will be only one cookie in a Set-Cookie header.)

`Returns:` http_set_cookie_t

`*TYPECAST_HTTP_URL_T`

Convert text_t to http_url_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_url_t : HTTP.REQ.URL provides operations for parsing and operating on the URL that is present in the first line of the HTTP request header. The supported format is \[<protocol>://<hostname>\]<path>?<query>. The Text object backing a HTTP URL object has the Text Mode set to URLENCODED by default.)

`Returns:` http_url_t

`*TYPECAST_HTTP_VERSION_T`

Convert text_t to http_version_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (http_version_t : HTTP.REQ.VERSION or HTTP.RES.VERSION provide operations to extract HTTP version information.)

`Returns:` http_version_t

`*TYPECAST_IPV6_ADDRESS_AT`

Convert text_t to ipv6_address_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ipv6_address_at : Provides operations for the 128-bit IPv6 address value. Some general information regarding IPv6 expressions: IPv6 PIXL expressions can be combined with other PIXL expressions using the '+' operator. The output is expected to be

the concatenation of the string representations of the individual PIXL expressions. No other operator other than '+' is expected to work when any of the operands is an IPv6 PIXL expression. Also, IPv6 PIXL expressions can be combined with any other type of PIXL expression except a PIXL expression that produces a bool result. In other words, if A and/or B are two IPv6 addresses, A+B should result in the string AB. When one of A or B is an IPv6 address, the other can only be a number or a string and not a boolean. Further, when A and/or B is an IPv6 address, the only operator allowed between them is '+'.

Example: Let the client source IPv6 address be ABCD:1234::ABCD. Let the server destination IPv4 address be 10.100.10.100. Then the expression CLIENT.IPV6.SRC + SERVER.IP.DST should produce the output "ABCD:1234::ABCD10.100.10.100". Similarly, CLIENT.IPV6.SRC + 5 should produce the result ABCD:1234::ABCD5)

`Returns:` ipv6_address_at

`*TYPECAST_IPV6_ADDRESS_T`

Convert text_t to ipv6_address_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ipv6_address_t : This object represents an IPv6 address present in the 1000:1001:CD10:0000:0000:89AB:4567:CDEF format.)

`Returns:` ipv6_address_t

`*TYPECAST_IPV6_SUBNET_AT`

Convert text_t to ipv6_subnet_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ipv6_subnet_at : Provides operations for the integral IPv6 subnet address value.)

`Returns:` ipv6_subnet_at

`*TYPECAST_IPV6_SUBNET_T`

Convert text_t to ipv6_subnet_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ipv6_subnet_t : This object represents an IPv6 subnet address present in the 1000:1001:CD10:0000:0000:89AB:4567:CDEF/64 format.)

`Returns:` ipv6_subnet_t

`*TYPECAST_IP_ADDRESS_AT`

Convert text_t to ip_address_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ip_address_at : Provides operations for the 32-bit integral IP address value.)

`Returns:` ip_address_at

`*TYPECAST_IP_ADDRESS_T`

Convert text_t to ip_address_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ip_address_t : Represents an IP address present in the 10.100.200.1 format.)

`Returns:` ip_address_t

`*TYPECAST_IP_OPTIONS_T`

Convert text_t to ip_options_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ip_options_t : IP protocol options)

`Returns:` ip_options_t

`*TYPECAST_IP_OPTIONS_TYPE_T`

Convert text_t to ip_options_type_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ip_options_type_t : IP Options Type)

`Returns:` ip_options_type_t

`*TYPECAST_IP_TOS_T`

Convert text_t to ip_tos_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ip_tos_t : Provides operations to TOS field in IP header.)

`Returns:` ip_tos_t

`*TYPECAST_LIST_T` (`char` sep)

Convert text_t to list_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (list_t : The character separator has to be provided when typecasting a textual context to list type. The current text mode has no effect on the character separator. For example if the current text mode is IGNORECASE and the separator is p then P will not be treated as a separator.)

`Parameters` (expressions not allowed) `:`

sep- Separator

`Returns:` list_t

`*TYPECAST_MAC_ADDRESS_AT`

Convert text_t to mac_address_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (mac_address_at : Provides operations for the 48-bit MAC address value.)

`Returns:` mac_address_at

`*TYPECAST_MAC_ADDRESS_T`

Convert text_t to mac_address_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (mac_address_t : Represents a MAC address present in the 12:34:56:78:9a:bc format.)

`Returns:` mac_address_t

`*TYPECAST_NUM_AT`

Convert text_t to num_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (num_at : Number Value)

`Returns:` num_at

`*TYPECAST_NUM_T` (num_format_e format)

Convert text_t to num_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (num_t : Treat the underlying text as a Number in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error.)

`Parameters` (expressions not allowed) `:`

format- Format

`Returns:` num_t

`*TYPECAST_NUM_T` (num_format_e format, num_at default_value)

Convert text_t to num_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (num_t : Treat the underlying text as a Number in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` num_t

`*TYPECAST_NVLIST_T` (`char` sep1, `char` sep2)

Convert text_t to nvlist_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (nvlist_t : Two character delimiters have to be provided when typecasting a Text object to a Name-Value List. The first delimited separates the name from the value. The second delimiter separates list items. For example typecast_nvlist_t('=', '&') handles a URL query string. The Text Mode has no effect on the character delimiters. For example if the current text mode is IGNORECASE and a delimiter is p then P will not be treated as a delimiter.)

`Parameters` (expressions not allowed) `:`

sep1- delimiter1

sep2- delimiter2

`Returns:` nvlist_t

`*TYPECAST_NVLIST_T` (`char` sep1, `char` sep2, `char` quote)

Convert text_t to nvlist_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (nvlist_t : Two character delimiters and quote-character have to be provided when typecasting a Text object to a Name-Value List that supports quote-character. The first delimited separates the name from the value. The second delimiter separates list items. The third value specifies the quote character. For example typecast_nvlist_t('=', ';', "") handles a name-value list separated by semi-colons that allows quoting. The quote-character specifies that the

value can occur within the quotes and the delimiters within the quote-characters should not be taken into account. The Text Mode has no effect on the character delimiters. For example if the current text mode is IGNORECASE and a delimiter is p then P will not be treated as a delimiter.)

`Parameters` (expressions not allowed) `:`

sep1- delimiter1

sep2- delimiter2

quote- quote-character.

`Returns:` nvlist_t

`*TYPECAST_PROTOCOL_BUFFER_T`

Convert text_t to protocol_buffer_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (protocol_buffer_t : gRPC Protocol Buffers interface)

`Returns:` protocol_buffer_t

`*TYPECAST_RADIUS_AVP_T`

Convert text_t to radius_avp_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (radius_avp_t : Operations that can be performed on the returned AVPs.

`Note:` An AVP can have multiple instances in a radius message. However, the system can access only the first 16 instances.

`Example:`

- To get the first value of AVP code 26 from a request, use: radius.REQ.AVP(26).VALUE(0).
- To get the fourth value of AVP code 26 from a request, use: radius.REQ.AVP(26).VALUE(3).

)

`Returns:` radius_avp_t

`*TYPECAST_RADIUS_AVP_VALUE_T`

Convert text_t to radius_avp_value_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (radius_avp_value_t : Provides operations to typecast RADIUS AVP value to Integer value or IP Address.)

`Returns:` radius_avp_value_t

`*TYPECAST_SEQ_TEXT_T`

Convert text_t to seq_text_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (seq_text_t : Represents the Text Sequence class.)

`Returns:` seq_text_t

`*TYPECAST_SERVICEPATH_T`

Convert text_t to servicepath_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (servicepath_t : Operations that can be performed on the service path.

`Example:`

- To get the name of the service path applicable to current subscriber, use: SUBSCRIBER.SERVICEPATH
- To determine If the service function is the next in the service path applicable to scubscriber, use: SUBSCRIBER.SERVICEPATH.IS_NEXT().

)

`Returns:` servicepath_t

`*TYPECAST_SIP_CALLID_HEADER_T`

Convert text_t to sip_callid_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_callid_header_t : This object provides operations for parsing the SIP callid header.)

`Returns:` sip_callid_header_t

`*TYPECAST_SIP_CONTENT_LENGTH_T`

Convert text_t to sip_content_length_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_content_length_t : The SIP.REQ.CONTENT_LENGTH or SIP.RES.CONTENT_LENGTH object can be treated as a SIP Header or as a Number. The numerical value for this object is derived from the value in the last instance of the Content-Length header.)

`Returns:` sip_content_length_t

`*TYPECAST_SIP_FROM_HEADER_T`

Convert text_t to sip_from_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_from_header_t : This object provides operations for parsing the SIP From header.)

`Returns:` sip_from_header_t

`*TYPECAST_SIP_HEADER_T` (text_t name)

Convert text_t to sip_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_header_t : When typecasting a Text object to SIP Header a header name must be provided.For example: SIP.REQ.HEADER("MyHdr").TYPECAST_SIP_HEADER_T("InHdr"))

`Parameters` (expressions not allowed) `:`

name- Header Name

`Returns:` sip_header_t

`*TYPECAST_SIP_HOSTNAME_T`

Convert text_t to sip_hostname_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_hostname_t : This object provides operations for parsing the SIP hostname as it appears at various places in the SIP protocol data. The format is abc.foo.com:5060.)

`Returns:` sip_hostname_t

`*TYPECAST_SIP_METHOD_T`

Convert text_t to sip_method_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_method_t : This object provides Text operations and SIP Request Method Enum operations on the SIP request method.)

`Returns:` sip_method_t

`*TYPECAST_SIP_TO_HEADER_T`

Convert text_t to sip_to_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_to_header_t : This object provides operations for parsing the SIP From header.)

`Returns:` sip_to_header_t

`*TYPECAST_SIP_URL_T`

Convert text_t to sip_url_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_url_t : SIP.REQ.URL provides operations for parsing and operating on the URL that is present in the first line of the SIP request header. The supported format is \[<protocol>://<hostname>\]<path>?<query>. The Text object backing a SIP URL object has the Text Mode set to URLENCODED by default.)

`Returns:` sip_url_t

`*TYPECAST_SIP_VERSION_T`

Convert text_t to sip_version_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_version_t : SIP.REQ.VERSION or SIP.RES.VERSION provide operations to extract SIP version information.)

`Returns:` sip_version_t

`*TYPECAST_SIP_VIA_HEADER_T`

Convert text_t to sip_via_header_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sip_via_header_t : This object provides operations for parsing the SIP Via header.)

`Returns:` sip_via_header_t

`*TYPECAST_SSLVPN_MODE_T`

Convert text_t to sslvpn_mode_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (sslvpn_mode_t : This object provides Text operations and SSLVPN Mode Enum operations on the SSLVPN request method.)

`Returns:` sslvpn_mode_t

`*TYPECAST_SSL_TEXT_T` (text_t name)

Convert text_t to ssl_text_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (ssl_text_t : Treat the underlying text object as SSL Text.)

`Parameters` (expressions not allowed) `:`

name- Name

`Returns:` ssl_text_t

`*TYPECAST_TCP_OPTIONS_T`

Convert text_t to tcp_options_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (tcp_options_t : TCP Protocol Options)

`Returns:` tcp_options_t

`*TYPECAST_TCP_OPTIONS_TYPE_T`

Convert text_t to tcp_options_type_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (tcp_options_type_t : TCP Protocol Options Type)

`Returns:` tcp_options_type_t

`*TYPECAST_TCP_REPEATER_OPTION_T`

Convert text_t to tcp_repeater_option_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (tcp_repeater_option_t : TCP Protocol Option : Repeater)

`Returns:` tcp_repeater_option_t

`*TYPECAST_TIME_AT`

Convert text_t to time_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (time_at : Treats a number value as number of seconds since GMT Jan 1 1970 0h 0m 0s.)

`Returns:` time_at

`*TYPECAST_TIME_LOCAL_AT`

Convert text_t to time_local_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (time_local_at : Treats a number value as number of seconds since GMT Jan 1 1970 0h 0m 0s as adjsuted for the local time zone.)

`Returns:` time_local_at

`*TYPECAST_TIME_T`

Convert text_t to time_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (time_t : This object treats a Text object as a date string. The formats supported are

1\. RFC822 :: Sun, 06 Nov 1994 08:49:37 GMT 2\. RFC850 :: Sunday, 06-Nov-94 08:49:37 GMT 3\. ASCTIME :: Sun Nov 6 08:49:37 1994 4\. ASCTIME like :: Sun Nov 6 08:49:37 1994 5\. ASCTIME like :: Sun Nov 06 08:49:37 1994 6\. Http Set-Cookie Expiry date :: Sun, 06-Nov-1994 08:49:37 GMT)

`Returns:` time_t

`*TYPECAST_UNSIGNED_LONG_AT`

Convert text_t to unsigned_long_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_at : Unsigned Long(64bit) Value)

`Returns:` unsigned_long_at

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error.)

`Parameters` (expressions not allowed) `:`

format- Format

`Returns:` unsigned_long_t

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format, ip_address_at default_value)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining

characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` unsigned_long_t

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format, unsigned_long_at default_value)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` unsigned_long_t

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format, num_at default_value)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` unsigned_long_t

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format, time_local_at default_value)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` unsigned_long_t

`*TYPECAST_UNSIGNED_LONG_T` (unsigned_long_format_e format, time_at default_value)

Convert text_t to unsigned_long_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unsigned_long_t : Treat the underlying text as a Unsigned Long in the given format. The supported formats are DECIMAL, HEX, DECIMAL_PREFIX, HEX_PREFIX. All the formats strip off the beginning white space. DECIMAL and HEX also strip off trailing white space. DECIMAL and HEX require that all the remaining characters must be proper digits. DECIMAL_PREFIX and HEX_PREFIX require that at least one or more more characters in the prefix must be proper digits. In case of overflow, there will be a parsing error. In case of parsing error the default value will be assumed.)

`Parameters` (expressions not allowed) `:`

format- Format

default_value- Number

`Returns:` unsigned_long_t

`*TYPECAST_UNUM_TEXT_T`

Convert text_t to unum_text_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (unum_text_t : Provides operations to treat the underlying OctectString as Binary String or unsigned long value .)

`Returns:` unum_text_t

`*TYPECAST_URL_CATEGORY_T`

Convert text_t to url_category_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (url_category_t : Retrieves URL category and attributes from an URL)

`Returns:` url_category_t

`*TYPECAST_VENDOR_SPEC_APPID_AVP_T`

Convert text_t to vendor_spec_appid_avp_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (vendor_spec_appid_avp_t : Retrieves AVPs that are nested in the grouped AVP Vendor-Specific-Application-Id (code 260). The nested AVPs are:

- Vendor-Id
- Auth-Application-Id
- Acct-Application-Id

For example, to retrieve the Auth-Application-Id AVP from the Vendor-Specific-Application-Id AVP:

- For requests:
  DIAMETER.REQ.VENDOR_SPECIFIC_APPLICATION_ID.AUTH_APPLICATION_ID
- For responses:
  DIAMETER.RES.VENDOR_SPECIFIC_APPLICATION_ID.AUTH_APPLICATION_ID

)

`Returns:` vendor_spec_appid_avp_t

`*TYPECAST_VENDOR_SPEC_RADIUS_AVP_T`

Convert text_t to vendor_spec_radius_avp_t. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (vendor_spec_radius_avp_t :

- Vendor-Id

To retrieve the Vendor-Id from the Vendor-Specific AVP:

- RADIUS.REQ.VENDOR_SPECIFIC.VENDORID

)

`Returns:` vendor_spec_radius_avp_t

`*UNQUOTE` (`char` c)

If selected text is quoted by character c, Remove character c from beginning and end.

For example: Say the selected text is / "foo xyz bar " /. Then on executing UNQUOTE("") the selected text will become /foo xyz bar / This method is affected by whether the text mode is case sensitive or insensitive.

`Parameters` (expressions not allowed) `:`

c- Character

`Returns:` text_t

`*URLSET_MATCHES_ANY` (text_t urlset_name)

Results in Boolean TRUE value if and only if the Text matches any of the patterns that are specified in the urlset named by the string argument. The matching is case-insensitive for domains, but case-sensitive for paths. For example:

- HTTP.REQ.HOST.APPEND(HTTP.REQ.URL).URLSET_MATCHES_ANY("urlset_forbidden") returns true when the combined domain and URL matches any pattern in the urlset whose name is "urlset_forbidden".

`Parameters` (expressions not allowed) `:`

urlset_name- urlset name

`Returns:` bool_at

`*URL_CATEGORIZE` (`uint` min_reputation, `uint` max_reputation)

Returns the URL category for the supplied URL with the given minimum and maximum reputation score. Where a score of 5 is most risky and 1 is least risky. If either score is set to 0, that bound would be ignored. By specifying the reputation scores, the function will returned the category with the highest score (most risky) based on the bounds. If there was an error getting the category or if the URL is invalid then it will result in an Undef error. For example: HTTP.REQ.HOST.APPEND(HTTP.REQ.URL).URL_CATEGORIZE(0, 0) returns value when the combined domain and URL is looked up for the URL category with the highest reputation score (most risky).

`Parameters` (expressions not allowed) `:`

min_reputation- Minimum reputation score of URL category

max_reputation- Maximum reputation score of URL category

`Returns:` url_category_t

`*URL_RESERVED_CHARS_SAFE`

Converts URL reserved characters to corresponding '%XX' values and retains the rest. This is a read only operation.

```
Based on RFC3986, following are considered URL unreserved characters:

    Alpha-numeric characters: a-z, A-Z, 0-9

    Hyphen and underscore: "-", "_"

    Dot: "."

    Tilde: "~"
```

The rest are converted to %XX encoding, 'XX' is the hex-based representation of the input character. If the requirement is to encode all but URL safe characters, please consider using HTTP_URL_SAFE method.

`Returns:` text_t

`*XML_DECRYPT` (text_t certKeyName)

Decrypt the selected content, which was encrypted using the W3C XML Encryption standard.

`Parameters` (expressions not allowed) `:`

certKeyName- identifies the certkey object containing the RSA private key to be used to decrypt the bulk encryption key in the selected EncryptedData element.

`Returns:` text_t

`*XML_ENCRYPT` (text_t certKeyName, encrypt_method_e method)

Encrypt the selected cleartext using the W3C XML Encryption standard.

`Parameters` (expressions not allowed) `:`

certKeyName- identifies the certkey object containing an X.509 certificate with the RSA public key to be used to encrypt the generated bulk encryption key. Note that the certKey object need not, and usually will not, include the associated RSA private key.

method- specifies the bulk encryption method (rc4, des3, aes128, aes192, or aes256) used to encrypt the content.

`Returns:` text_t

`*XML_ENCRYPT` (text_t certKeyName, encrypt_method_e method, `uint` flags)

Encrypt the selected cleartext using the W3C XML Encryption standard.

`Parameters` (expressions not allowed) `:`

certKeyName- identifies the certkey object containing an X.509 certificate with the RSA public key to be used to encrypt the generated bulk encryption key. Note that the certKey object need not, and usually will not, include the associated RSA private key.

method- specifies the bulk encryption method (rc4, des3, aes128, aes192, or aes256) used to encrypt the content.

flags- optional bit mask to specify optional elements in the EncryptedData element. These are hints to tell the receiver what private key to use to decrypt the bulk encryption key, providing information from the certKey's X.509 certificate.

- 1 - include a KeyName element with the certKeyName;
- 2 - include a KeyValue element with the RSA public key from the certificate;
- 4 - include an X509IssuerSerial element with the certificate serial number and issuer DN;
- 8 - include an X509SubjectName element with the certificate subject DN;
- 16 - include an X509Certificate element with the entire certificate;

`Returns:` text_t

`*XPATH_HTML_WITH_MARKUP` (`xpath_str` xpathex)

Applies an XPath expression to the DOM for an HTML document and returns the selected node-set or string, including markup like element tags. node-sets are converted to strings using the standard XPath string conversion routine. The selected portion of the document can be used as the target for rewrite actions.

Examples: HTTP.REQ.BODY(1000).XPATH_HTML_WITH_MARKUP(xp%//md/head/title%) returns the <title> element in the document's <head> This can be used in a rewrite action to replace or delete the <title> element.

`Parameters` (expressions not allowed) `:`

xpathex- XPath Expression

`Returns:` text_t

`*XPATH_HTML` (`xpath_bool` xpathex)

Applies an XPath expression to the DOM for an HTML document and a boolean value.

Examples: HTTP.RES.BODY(1000).XPATH_HTML(xp%boolean(/md/head/meta)%) returns true if the <meta> element exists as a child of <head> element.

`Parameters` (expressions not allowed) `:`

xpathex- XPath Expression

`Returns:` bool_at

`*XPATH_HTML` (`xpath_double` xpathex)

Applies an XPath expression to the DOM for an HTML document and a double value.

Examples: HTTP.RES.BODY(1000).XPATH_HTML(xp%number(//video/@height)%) returns the numeric value of the height attribute of the first <video> element.

`Parameters` (expressions not allowed) `:`

xpathex- XPath Expression

`Returns:` double_at

`*XPATH_HTML` (`xpath_str` xpathex)

Applies an XPath expression to the DOM for an HTML document and returns the selected node-set or string. node-sets are converted to strings using the standard XPath string conversion routine.

Examples: HTTP.REQ.BODY(1000).XPATH_HTML(xp%//img/@src%) returns the string value of the src attribute of the first

```

ICA_PROTOCOL_T

Models the ICA protocol.

This topic lists the expressions that are provided by this class.

- `SERVER`

  Operates on the ICA protocol data associated with the current packet.

`Returns:` ica_server_t

ICA_SERVER_T

Operates on the ICA flow.

This topic lists the expressions that are provided by this class.

- `IP`

  Returns the IP of the backend server.

`Returns:` ip_address_at

- `IPV6`

  Returns IPv6 Address of the backend server.

`Returns:` ipv6_address_at

- `PORT`

  Returns the destination port.

`Returns:` num_at

ICAP_PROTOCOL_T

Models the ICAP message types.

This topic lists the expressions that are provided by this class.

- `RES`

  Operates on ICAP Response.

`Returns:` icap_res_t

ICAP_RES_T

Operates on ICAP Response.

This topic lists the expressions that are provided by this class.

- `DATE`

  Returns the contents of the ICAP Date header as text or as a date object. The date formats recognized are: RFC822. Sun, 06 Jan 1980 08:49:37 GMT RFC850. Sunday, 06-Jan-80 9:49:37 GMT ASCTIME. Sun Jan 6 08:49:37 1980

`Returns:` http_date_t

- `FULL_HEADER`

  Returns the entire ICAP response header (including the terminating \\r\\n\\r\\n)

`Returns:` text_t

`HEADER` (text_t header_name)

Returns the contents of the ICAP header specified by the String argument. The header name cannot be longer than 32 characters.

`Parameters` (expressions not allowed) `:`

header_name- Header Name

`Returns:` http_header_t

- `IS_CLIENT_ERROR`

  Returns True if response code is 4xx.

`Returns:` bool_at

- `IS_SERVER_ERROR`

  Returns True if response code is 5xx.

`Returns:` bool_at

- `IS_SUCCESSFUL`

  Returns True if response code is 2xx.

`Returns:` bool_at

- `SET_COOKIE`

  Obtain the ICAP Set-Cookie Header Object from this response.

`Returns:` http_set_cookie_t

- `STATUS`

  Returns the ICAP response status code.

`Returns:` num_t

- `STATUS_MSG`

  Returns the ICAP response status message.

`Returns:` text_t

- `VERSION`

  Returns the ICAP version.

`Returns:` http_version_t

INTERFACE_REQ_T

The physical interface request

This topic lists the expressions that are provided by this class.

- `ID`

  Extracts the interface ID of the interface through which the current packet entered the Application Switch, and returns that ID.

`Returns:` interface_t

- `RXTHROUGHPUT`

  Returns an integer representing the raw received traffic throughput in kilobytes per second for the previous seven seconds.

`Returns:` num_at

- `RXTXTHROUGHPUT`

  Returns an integer representing the raw received and transmitted traffic throughput in kilobytes per second for the previous seven seconds.

`Returns:` num_at

- `TXTHROUGHPUT`

  Returns an integer representing the raw transmitted traffic throughput in kilobytes per second for the previous seven seconds.

`Returns:` num_at

INTERFACE_RES_T

The physical interface response

This topic lists the expressions that are provided by this class.

- `ID`

  Extracts the interface ID of the interface through which the current packet entered the Application Switch, and returns that ID.

`Returns:` interface_t

- `RXTHROUGHPUT`

  Returns an integer representing the raw received traffic throughput in kilobytes per second for the previous seven seconds.

`Returns:` num_at

- `RXTXTHROUGHPUT`

  Returns an integer representing the raw received and transmitted traffic throughput in kilobytes per second for the previous seven seconds.

`Returns:` num_at

- `TXTHROUGHPUT`

  Returns an integer representing the raw transmitted traffic throughput in kilobytes per second for the previous seven seconds.

`Returns:` num_at

INTERFACE_T

Network Interface ID

This topic lists the expressions that are provided by this class.

`EQ` (text_t id)

Returns Boolean TRUE if the interface's ID matches the argument. The input string cannot be bigger than 9 characters. If Cluster is enabled then it will support 3-tuple interface ID too \[Local-node,controller,unit\]. Examples: CLIENT.INTERFACE.ID.EQ("1/1") SERVER.INTERFACE.ID.EQ("LA/1") CLIENT.INTERFACE.ID.EQ("0/1/1") SERVER.INTERFACE.ID.EQ("1/LA/1") CONNECTION.INTF.EQ("1/1")

`Parameters` (expressions not allowed) `:`

id- Interface ID

`Returns:` bool_at

`NE` (text_t id)

Returns Boolean TRUE if the interface's ID doesn't match the argument. The input string cannot be bigger than 9 characters. If Cluster is enabled then it will support 3-tuple interface ID too \[Local-node,controller,unit\]. Examples: CLIENT.INTERFACE.ID.NE("1/1") SERVER.INTERFACE.ID.NE("LA/1") CLIENT.INTERFACE.ID.NE("0/1/1") SERVER.INTERFACE.ID.NE("1/LA/1") CONNECTION.INTF.NE("LO/1")

`Parameters` (expressions not allowed) `:`

id- Interface ID

`Returns:` bool_at

IP_ADDRESS_AT

Provides operations for the 32-bit integral IP address value.

This topic lists the expressions that are provided by this class.

`*Note` *: Expressions with the * symbol are inherited / promoted from num_at

`APPEND` (text_t str)

Appends the given string to the string representation of the current IP address.

`Parameters``:`

str- the string to append.

`Returns:` text_t

`*APPLY_MASK` (ip_address_at i)

Returns IP Address Value after applying subnet mask which can take values between 0.0.0.0 and 255.255.255.255.

`Parameters` (expressions not allowed) `:`

i- IP Address

`Returns:` ip_address_at

`*APPLY_MASK` (num_at mask)

Returns IP Address Value after applying subnet mask which can take values between 0 and 0xffffffffUL.

`Parameters` (expressions not allowed) `:`

mask- Subnet Mask

`Returns:` ip_address_at

`*APPLY_MASK` (time_local_at mask)

Returns IP Address Value after applying subnet mask which can take values between 0 and 0xffffffffUL.

`Parameters` (expressions not allowed) `:`

mask- Subnet Mask

`Returns:` ip_address_at

`*APPLY_MASK` (time_at mask)

Returns IP Address Value after applying subnet mask which can take values between 0 and 0xffffffffUL.

`Parameters` (expressions not allowed) `:`

mask- Subnet Mask

`Returns:` ip_address_at

`*APPLY_MASK` (unsigned_long_at mask)

Returns IP Address Value after applying subnet mask which can take values between 0 and 0xffffffffUL.

`Parameters` (expressions not allowed) `:`

mask- Subnet Mask

`Returns:` ip_address_at

`*CLOUD_SERVICE_PROVIDER` (ip_protocol_cloud_service_provider_e service_provider)

Cloud IP. Returns TRUE if the client IP is categorized as cloud IP and cloud service provider matches service provider argument. else returns FALSE.

`Parameters` (expressions not allowed) `:`

service_provider- is service provider

`Returns:` bool_at

`*EQ` (double_at i)

Returns Boolean TRUE if the double value is equal to the argument.

`Parameters``:`

i- Double

`Returns:` bool_at

`*EQ` (ip_address_at i)

Returns Boolean TRUE if the IP address value is same as the argument. For example: CLIENT.IP.DST.EQ(10.100.10.100)

`Parameters``:`

i- IP Address

`Returns:` bool_at

`*EQ` (unsigned_long_at i)

Returns Boolean TRUE if the unsigned long is equal to the argument.

`Parameters``:`

i- Unsigned Long

`Returns:` bool_at

`*GET1`

Returns a Number Value 10 if the IP address value is 10.100.200.1

`Returns:` num_at

`*GET2`

Returns a Number Value 100 if the IP address value is 10.100.200.1

`Returns:` num_at

`*GET3`

Returns a Number Value 200 if the IP address value is 10.100.200.1

`Returns:` num_at

`*GET4`

Returns a Number Value 1 if the IP address value is 10.100.200.1

`Returns:` num_at

`*IN_SUBNET` (`ip_subnet` s)

Returns Boolean TRUE if the IP address value is in the subnet specified by the argument. For example: CLIENT.IP.DST.IN_SUBNET(10.100.10.100/18)

`Parameters` (expressions not allowed) `:`

s- IP Subnet

`Returns:` bool_at

`*IPREP_IS_MALICIOUS`

IP Reputation. Returns TRUE if the client IP is categorized as malicious else returns FALSE.

`Returns:` bool_at

`*IPREP_THREAT_CATEGORY` (ip_protocol_iprep_category_e category)

IP Reputation. Returns TRUE if the client IP is categorized as malicious and threat category matches category argument, else returns FALSE.

`Parameters` (expressions not allowed) `:`

category- is IP category

`Returns:` bool_at

`*IS_CLOUD_IP`

Cloud IP. Returns TRUE if the client IP is categorized as cloud service provide IP. else returns FALSE.

`Returns:` bool_at

`*IS_IPV6`

Returns TRUE or FALSE depending on whether this is an IPv6 client.

`Returns:` bool_at

`*LAT_LONG`

Results in text_t containing location as cordinates. Location will be of the form: Latitude,Longitude Expression example: CLIENT.IP.SRC.LAT_LONG For example: 36,-119

`Returns:` text_t

`*LOCATION`

Results in list_t containing location. Location will be of the form: qual1.qual2.qual3.qual4.qual5.qual6 Expression example: CLIENT.IP.SRC.LOCATION For example: NorthAmerica.US.*.*.*.*

`Returns:` list_t

`*LOCATION` (num_at n)

Results in list_t containing location. Location will be of the form: qual1.qual2.qual3.qual4.qual5.qual6 Expression example: CLIENT.IP.SRC.LOCATION(2) For example: NorthAmerica.US

`Parameters` (expressions not allowed) `:`

n- is the level up to which location will be returned, the first qualifier is numbered 1.

`Returns:` list_t

`*MATCHES_LOCATION` (text_t location)

Results in Boolean TRUE value if the location of the IP matches the location argument. Location string can be of the form: qual1.qual2.qual3.qual4.qual5.qual6 For example: NorthAmerica.CA.*

`Parameters` (expressions not allowed) `:`

location- Location

`Returns:` bool_at

`*MATCHES` (text_t hostname)

Returns Boolean TRUE if hostname IP address matches the current IP address. The hostname string cannot be bigger than 255 characters.

`Parameters` (expressions not allowed) `:`

hostname- HostName

`Returns:` bool_at

`*SUBNET` (num_at n)

Returns IP Address Value after applying the subnet which can take values between 0 and 32. For Example: CLIENT.IP.SRC.SUBNET(24) will give 192.168.1.0 for 192.168.1.\[0-255\]

`Parameters` (expressions not allowed) `:`

n- Subnet Value

`Returns:` ip_address_at

`*TYPECAST_IPV6_ADDRESS_AT`

Typecast IPv4 address to its "IPv4-mapped IPv6 address" representation.

`Returns:` ipv6_address_at

`*TYPECAST_NUM_AT`

Convert ip_address_at to num_at. Will raise an undef if the value is null, empty, or the value has an invalid format for the destination type. (num_at : Number Value)

`Returns:` num_at

`*TYPECAST_TEXT_T`

Typecast the IP Address Value to its string representation.

`Returns:` text_t

`*TYPECAST_UNSIGNED_LONG_AT`

Typecast the IPv4 address value to an Unsigned Long value.

`Returns:` unsigned_long_at

`*ABS`

Return the absolute value of the number.

`Returns:` num_at

`*ADD` (double_at i)

Return the Double Value after adding the argument to the current double value.

`Parameters``:`

i- Double

`Returns:` double_at

`*ADD` (ip_address_at i)

Return the Unsigned Long after adding the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*ADD` (unsigned_long_at i)

Return the Unsigned Long after adding the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*ADD` (num_at i)

Return the Number Value after adding the argument to the current number value.

`Parameters``:`

i- Number

`Returns:` num_at

`*ADD` (time_local_at i)

Return the Unsigned Long after adding the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*ADD` (time_at i)

Return the Unsigned Long after adding the argument to the current unsigned long value.

`Parameters``:`

i- Unsigned Long

`Returns:` unsigned_long_at

`*AS_MICROSEC_STR`

Returns the current system time in the following format Format: Wday, day Month year hh:mm:ss.ffffff GMT ffffff represents microseconds Examples:

Mon, 05 Mar 2018 10:23:36.568419 GMT

`Returns:` text_t

`*AS_MILLISEC_STR`

Returns the current system time in the following format Format: Wday, day Month year hh:mm:ss.fff GMT fff represents milliseconds Examples:

Mon, 05 Mar 2018 10:23:36.568 GMT

`Returns:` text_t

`*AS_NANOSEC_STR`

Returns the current system time in the following format Format: Wday, day Month year hh:mm:ss.fffffffff GMT fffffffff represents nanoseconds Accuracy may be at larger granularity than nanosecond resolution. Examples:

Mon, 05 Mar 2018 10:23:36.568419567 GMT

`Returns:` text_t

`*BETWEEN` (double_at i, double_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (double_at i, ip_address_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (double_at i, unsigned_long_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (ip_address_at i, double_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (ip_address_at i, ip_address_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (ip_address_at i, unsigned_long_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (unsigned_long_at i, double_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (unsigned_long_at i, ip_address_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (unsigned_long_at i, unsigned_long_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (double_at i, num_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (ip_address_at i, num_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (unsigned_long_at i, num_at j)

Returns Boolean TRUE if the unsigned long value is greater than or equal to the Lower argument and the unsigned long value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (double_at i, time_local_at j)

Returns Boolean TRUE if the double value is greater than or equal to the Lower argument and the double value is lesser than or equal to the Upper argument.

`Parameters``:`

i- Lower

j- Upper

`Returns:` bool_at

`*BETWEEN` (ip_address_at i, time_local_at j)
